Biomimetic Synthesis of the Tetracyclic Core of Berkelic Acid

Jingye Zhou and Barry B. Snider

Department of Chemistry MS 015, Brandeis University, Waltham, Massachusetts 02454-9110

Abstract

Acid catalyzed condensation of 2,6-dihydroxybenzoic acid **3** with ketal aldehyde **14** in methanol at 25 °C, followed by CH₂N₂ esterification gave a 4:1:4:1 mixture of diastereomers **15b-18b** in 60% yield. Equilibration of this mixture with TFA in CDCl₃ provided tetracycle **15b** (83% yield) with the complete skeleton of berkelic acid. A similar condensation at 0 °C afforded **15b-18b** and a reduction product **19b**, which was probably formed by a 1,5-hydride shift.

Stierle and coworkers recently isolated berkelic acid (**1**), a novel spiroketal with selective anticancer activity, from an acid mine waste fungal extremophile (see Scheme 1).¹ The structure was assigned based on the analysis of the NMR and mass spectral data. The absolute stereochemistry and the relative stereochemistry of the side chain stereocenter were not assigned. Berkelic acid inhibits MMP-3 and caspase-1 and shows selective activity toward ovarian cancer OVCAR-3 with a GI₅₀ of 91 nM. We thought that **1** should be accessible by a highly convergent route starting from ketal aldehyde **2** and 2,6-dihydroxybenzoic acid **3**. Acid **3**, a synthetic, and presumably biosynthetic, precursor to pulvilloric acid (**4**), has been prepared in both racemic² and optically pure forms.³

An oxa-Pictet-Spengler cyclization⁴ of **2** and **3** should give isochroman **8** (see Scheme 2). These cyclizations are usually suggested to proceed by formation of oxocarbenium ion **6**, followed by a Friedel-Crafts cyclization to give **8**. It is also possible that the first step is an intermolecular Friedel-Crafts reaction to give benzylic alcohol **5**. Protonation of the alcohol and loss of water will give the stabilized benzylic cation **7**⁵ that will cyclize to give **8**. Ketal exchange with loss of methanol will give **9** with the complete tetracyclic core of berkelic acid.

Supporting Information Available: Complete experimental procedures, copies of ¹H and ¹³C NMR spectral data, and X-ray crystallographic data (CIF file) for **15b**. This material is available free of charge via the Internet at <http://pubs.acs.org>.

This sequence generates two new stereocenters so that four isomers can be produced. The anomeric center of berkelic acid (**1**), with the oxygen of the tetrahydrofuran ring axial on the pyran ring, is probably in the more stable configuration. Therefore this center should be readily set by equilibration. Oxa-Pictet-Spengler cyclizations that give 1,3-disubstituted isochromans often give mainly the cis disubstituted products such as **8** under kinetically controlled conditions.⁶ In some cases, equilibration via the benzylic cations analogous to **7** and **10** afforded mainly the more stable trans product.⁷ Therefore it might be possible to use either kinetically or thermodynamically controlled conditions to obtain the desired diastereomer.

Model ketal aldehyde **14** was prepared to investigate this sequence (see Scheme 3). Addition of the lithium enolate of *tert*-butyl acetate to γ -butyrolactone (**11**) afforded ester **12** as a mixture of hydroxy ketone and hemiketal tautomers.⁸ Reaction in acidic methanol converted this mixture to ketal ester **13** in 56% overall yield. Reduction of **13** with DIBAL-H at -78 °C provided crude ketal aldehyde **14**, which decomposed on chromatography and was used without purification.

Reaction of acid **3**⁹ with 2-3 equiv of crude ketal aldehyde **14** in MeOH containing Dowex 50WX8-400-H⁺ for 12 h at 25 °C afforded a mixture of the desired tetracyclic acids **15a-18a** that was treated with diazomethane in ether to give a 4:1:4:1 mixture of methyl esters **15b-18b**, respectively, in 60% yield. The four isomers were separated and characterized spectroscopically. Molecular mechanics with conformational searching calculated relative strain energies for **15b-18b** of 28.14, 28.56, 30.51, and 30.84 kcal/mol, respectively.¹⁰ This suggests that isomers **15b** and **16b** with H_{3'a} and H_{5'} cis are significantly more stable than isomers **17b** and **18b** with these hydrogens trans. Isomers **15b** and **17b** with the tetrahydrofuran oxygen axial on the pyran ring are slightly more stable than **16b** and **18b**, respectively, as expected from the anomeric effect. The formation of **17b** as one of the two major products indicates that incomplete equilibration occurs under these reaction conditions.

The coupling constants to H_{3'a} are 10-12 and 5-6 Hz indicating that this hydrogen is axial in all four conformers. The coupling constants between the benzylic methylene group and the axial hydrogen H_{5'} in **15b** (*J* = 10.7, 4.2 Hz) and **16b** (11.7 and 3.9 Hz) are close to the values calculated for both **15b** and **16b** of 11.2 and 4.6 Hz. The coupling constants between the benzylic methylene group and H_{5'} in **17b** (8.8 and 4.9 Hz) and **18b** (8.8 and 3.9 Hz) are close to the calculated values of 7.0 and 4.7 Hz for **17b** and 7.2 and 4.5 Hz for **18b**, suggesting that these molecules are mixtures of the conformer drawn with a boat ring and the pentyl substituent in a pseudoequatorial conformation and the chair conformer with an axial pentyl substituent.

The spiroketal stereochemistry can be assigned from the chemical shift of the axial proton H_{3'a}, which is in a 1,3- relationship to the anomeric center. The difference between the two diastereomers is especially pronounced in C₆D₆.¹¹ In this solvent, H_{3'a} of **15b** and **17b** with an axial oxygen absorbs at δ 5.00 and δ 5.12, respectively whereas H_{3'a} of **16b** and **18b** with an equatorial oxygen absorbs at δ 4.41 and 4.63, respectively. Finally, NOEs between H_{3'a} and H_{5'} in **15b**, between H_{3'a} and both H₃ and H_{5'} in **16b**, between H_{3'a} and both H_{6'} and the side chain CH₂ group in **17b**, and between H_{3'a} and H₃, H_{6'}, and the side chain CH₂ group in **18b** confirmed the stereochemical assignments.

The molecular mechanics calculations suggest that the desired isomer **15b** is most stable. Our structures **15b-18b** differ from simple isochromans in which the trans isomer may be more stable⁷ because of the additional fused ring in **15b-18b**. Therefore equilibration of the mixture of four isomers should significantly increase the percentage of **15b** in the mixture. We were delighted to find that equilibration of the above 4:1:4:1 mixture of **15b-18b** with 0.2% TFA in CDCl₃ for 12 h provided a 20:2:1:0 mixture of **15b-18b**, respectively, from which **15b** could be isolated in 50% overall yield from acid **3**. The stereochemistry of **15b** was confirmed by X-

ray crystal structure determination. Basic hydrolysis of pure **15b** completed the synthesis of berkelic acid model **15a**, which was contaminated with 5% of **16a** resulting from spiroketal equilibration during hydrolysis, in 83% yield (see Scheme 4).

Our initial reactions of **3** and **14**, which were carried out at 0 °C rather than 25 °C, afforded a 4:1:7:1 mixture of **15b-18b**, respectively in only 41% yield. Additionally, we isolated 30% of 80% pure reduced product **19b** as a mixture of diastereomers. Acetylation of impure **19b** afforded **20b** which could be isolated in pure form in 72% yield (see Scheme 5).

The formation of **19b** was unexpected and the presence of the two diastereomers complicated the structure proof. We therefore prepared acid **21**¹² by carboxylation of olivetol and treated it with **14** to generate the reduced product **22** in 27% yield (see Scheme 6).¹³

Reduced products **19b** and **22** are probably formed by a second equivalent of aldehyde acting as a hydride donor. 1,3-Dioxane **23** could be formed from a benzylic alcohol analogous to **5** and a second equivalent of aldehyde (see Scheme 7). Protonation of **23** would give benzylic cation **24**, which could undergo a 1,5-hydride shift to give **25**. Hydrolysis of the aryl ester of **25** and spiroketalization would form **19a**. Alternatively, a benzylic alcohol analogous to **5** could react with a second equivalent of aldehyde to give 1,3-dioxane **26**. Protonation of **26** would give benzylic cation **27** that could undergo a 1,5-hydride shift to give ester **28**. Hydrolysis of the ester of **28** and spiroketalization would form **19a**. Only traces of these reduced products are formed when the reaction is carried out at 25 °C. This is consistent with the proposed mechanism because the highly ordered transition state for a 1,5-hydride shift should have a large negative entropy of activation and therefore be relatively favored at lower temperatures. 1,5-Hydride shifts of this type are uncommon, but some related examples have recently been reported.¹⁴

The formation of reduced product **19a** is inconsistent with the usually proposed mechanism for the oxa-Pictet-Spengler cyclization. If the isochroman ring is formed by an intramolecular Friedel-Crafts reaction of an oxocarbenium ion analogous to **6**, reduction by a 1,5-hydride shift is unlikely. Such a pathway is impossible for the conversion of **21** to **22** since there is no alcohol in the side chain. This suggests that the oxa-Pictet-Spengler cyclization of **3** to give **15-18** proceeds at least partially by a Friedel-Crafts reaction to give a benzylic alcohol analogous to **5** followed by cyclization to form the isochroman ring.¹⁵

In conclusion, acid catalyzed condensation of acid **3** with ketal aldehyde **14** in methanol at 25 °C, followed by CH₂N₂ esterification, and equilibration with TFA in CDCl₃ affords tetracycle **15b** (50% overall yield) with the complete skeleton of berkelic acid. Application of this route to the total synthesis of berkelic acid (**1**) using a more highly functionalized ketal aldehyde **2**, in which R is a precursor to the side chain, is currently in progress.
