Abstract

High-speed countercurrent chromatography (HSCCC) was successfully used to isolate three bioactive compounds, i.e., amygdalin from bitter almond and taxifolin-3-glucoside and quercetin-3-galactoside (hyperoside) from water extract of *Agrimonia pilosa* Ledeb, respectively. From 1 g of the crude extract 65 mg of amygdalin was isolated at 97% purity using a two-phase solvent system composed of ethyl acetate-n-butanol-water (5:2:5, v/v) by preparative HSCCC. From a 400 mg amount of crude extract of *Agrimonia pilosa* Ledeb, 11 mg of taxifolin-3-glucoside and 8 mg of hyperoside were isolated at 96% purity using a two-phase solvent system composed of ethyl acetate-methanol-water (25:1:25, v/v) similarly by preparative HSCCC. The final structural identification was performed by MS, ¹H-NMR and ¹³C-NMR Spectra.

Keywords

High-speed countercurrent chromatography (HSCCC); Amygdalin; Taxifolin-3-glucoside; Hyperoside; *Agrimonia pilosa* Ledeb

INTRODUCTION

Bitter almond is a traditional Chinese medicine, containing about 48% fat, 30% protein, 6% carbohydrate, 3% amygdalin and some other nutrition[1]. Amygdalin is a commercially available natural cyanogenic glycoside which can dispel the phlegm, relieve the cough, anticancer, improve the immunity, reduce the blood sugar, prevent chronic gastritis and withering gastritis[2,3]. The molecular formula of amygdalin is C₂₀H₂₇NO₁₁ and the chemical structure is shown in Fig.1. The separation of amygdalin has been performed by recrystallization and macroporous resin [4,5]. However, the processes need several steps and are time consuming.

Agrimonia pilosa Ledeb is a native plant that grows in many parts of China. It contains flavonoids and phenolic compounds. A pharmaceutical compound of *Agrimonia pilosa* Ledeb for treating or preventing hepatitis is reported. Bioassays showed that flavonoid effectively controls fungal pathogens in vitro, including *Alternaria alternata* and *Fusarium avenaceum*,

* Corresponding author: Yun WEI, Analytical Chemistry Department, Faculty of Sciences, Beijing University of Chemical Technology, Tel&fax: 00861064442928. weiyun@mail.buct.edu.cn.

although antifungal activity of this compound in the plant is limited [6]. Hyperoside (quercetin-3-galactoside) also decreases blood pressure transiently [7]. However, the separation of these active compounds from natural sources has always been difficult to achieve. Ethanol extract of *Agrimonia pilosa* Ledeb has been studied in our lab [8], and the water extract is further studied in this paper.

High-speed countercurrent chromatography (HSCCC), being a support-free liquid–liquid partition method, eliminates irreversible adsorption of sample onto the solid support, and has been widely used in preparative separations of natural products [9-10]. The aim of this study was to develop a method for purifying natural amygdalin and bioactive constituents from water extract of *Agrimonia pilosa* Ledeb. The present paper describes the successful preparative separation and purification of amygdalin from the crude extract of bitter almond and taxifolin-3-glucoside and hyperoside from water extract of *Agrimonia pilosa* Ledeb by HSCCC.

EXPERIMENTAL

Apparatus

The analytical HSCCC instrument employed in the present study is a Model GS 20 analytical high-speed countercurrent chromatograph designed and constructed in Beijing Institute of New Technology Application (Beijing, China). The apparatus holds a pair of column holders symmetrically on the rotary frame at a distance of 5 cm from the central axis of the centrifuge. The multilayer coil separation column was prepared by winding a 50 m long, 0.85 mm I.D. PTFE (polytetrafluoroethylene) tube directly onto the holder hub forming multiple coiled layers with a total capacity of 30 mL. The β value varied from 0.4 at the internal terminal to 0.7 at the external terminal ($\beta = r/R$ where r is the distance from the coil to the holder shaft, and R , the revolution radius or the distance between the holder axis and central axis of the centrifuge). Although the revolution speed of the apparatus could be regulated with a speed controller in the range between 0 to 2000 rpm, a speed of 1600 rpm was used in the present studies. A manual sample injection valve with a 1.0 mL loop was used.

The preparative high-speed countercurrent instrument was used with a Model GS10 multilayer coil planet centrifuge equipped with a PTFE (polytetrafluoroethylene) multilayer coil of 110 m $\times$ 1.6 mm I.D. with a total capacity of 230 mL, which is also designed and constructed in Beijing Institute of New Technology Application (Beijing, China).

The high-performance liquid chromatography (HPLC) equipment used was a Shimadzu LC-20AVP system with two LC-20AT solvent delivery units, an SPD-M20AVP UV–VIS photodiode array detector (DAD), a Model 7725 injection valve with a 20 μ L loop and an auto-sampler, an SCL-20AVP system controller, and a Class-VP-LC work station (Shimadzu, Tokyo, Japan).

The ^1H -NMR and ^{13}C -NMR Spectra were recorded on a “amms 600” Varian Inova 600 (600 MHz) spectrometer.

Reagents

All organic solvents used for sample preparation and HSCCC were of analytical grade while methanol used for HPLC analysis was of chromatography grade. These solvents were all purchased from Beijing Chemical Factory (Beijing, China). Bitter almond was purchased from a company in ZuoQuan, Shanxi Province, China. *Agrimonia pilosa* Ledeb was purchased from a local store (Tong Ren Tang Shop, Beijing, China). Hyperoside standards were purchased from National Institute for the Control of Pharmaceutical & Biological Products (Beijing, China).

Preparation of sample

Bitter almond dross was obtained through the process of enzyme destruction, crushing and defatting. The extraction condition of amygdalin from bitter almond dross was optimized by orthogonal design. About 30g of bitter almond dross was extracted (refluxed) with 180 ml 80% ethanol for 45 min 3 times. The obtained liquid was combined and concentrated to dryness under reduced pressure, yielding 7.4 g of crude sample in which amygdalin purity was determined by HPLC based on the external standard curve (Fig.1).

About 200 g of dried *Agrimonia pilosa* Ledeb was extracted (refluxed) for 3 h, three times, with 500 mL of petroleum ether (b.p.: 60–90°C), and then filtered by six-layer pledget. The residues were extracted with 500 mL of 95% ethanol solution, and then filtered by six-layer pledget. The residues were again extracted with 500 mL of water, and concentrated to dryness under reduced pressure, yielding 12 g of a crude sample, which contained taxifolin-3-glucoside and hyperoside at purity of 3.1% and 3.3% respectively as determined by HPLC based on the external standard curve (Fig. 3).

Preparation of two-phase solvent system and sample solution

For the separation of amygdalin the solvent system utilized was prepared by mixing ethyl acetate-n-butanol-water (5:2:5, 5:1:5, 10:1:10 or 50:1:50, v/v), or n-butanol-water (1:1, v/v). For the separation of water extract of *Agrimonia pilosa* Ledeb the solvent system was prepared by mixing ethyl acetate-methanol-water (25:1:25, 10:1:10 or 5:1:5, v/v), and thoroughly equilibrating the mixture in a separatory funnel at room temperature, two phase being separated shortly before use.

The sample solutions were prepared by dissolving the crude extract in the lower phase at suitable concentrations according to the analytical or preparative purpose.

Separation procedure

Analytical HSCCC was performed with a Model GS 20 HSCCC instrument as follows: the multilayer coiled column was first entirely filled with the upper phase. The lower phase was then pumped into the head end of the inlet column at a flow rate of 1.0 mL/min, while the apparatus was run at a revolution speed of 1600 rpm. After hydrodynamic equilibrium was established, as indicated by a clear mobile phase eluting at the tail outlet, the sample solution (12 mg in 1 mL of lower phase) was injected through the sample port. The effluent from the tail end of the column was continuously monitored with a UV detector at 280 nm. Each peak fraction was collected according to the chromatogram.

Preparative HSCCC separation was performed as follows: the multi-layer coiled column was first entirely filled with the upper phase. The lower phase was then pumped into the head end of the column at a flow rate of 2.0 mL/min, while the apparatus was run at a revolution speed of 800 rpm. After hydrodynamic equilibrium was established, as indicated by a clear mobile phase eluting at the tail outlet, the sample solution was injected through the sample port. The effluent from the tail end of the column was continuously monitored with a UV detector at 254/280 nm. Each peak fraction was collected according to the chromatogram. The retention of the stationary phase was computed from the volume of the stationary phase collected from the column after the separation was completed.

HPLC analyses and identification of HSCCC peak fractions

HPLC conditions of the crude extract of bitter almond with the chemical structure of amygdalin are as follows: the solvent system consisted of water as mobile phase A and methanol as mobile phase B (95:5, v/v). Flow rate was 1.0 ml/min, and 10 μ L portions were injected into the column. Amygdalin was detected by absorbance at 254 nm.

The water extract of *Agrimonia pilosa* Ledeb and HSCCC peak fractions were each analyzed by HPLC. The analyses were performed with a YMC ODS column (150 × 4.6 mm I.D.). The mobile phase composed of methanol-water (50:50, v/v) was isocratically eluted at a flow-rate of 1.0 mL/min and the effluent monitored at 280 nm by a DAD detector. Identification of the target compounds was based on MS, ¹H-NMR; and ¹³C-NMR spectra.

RESULTS AND DISCUSSION

The HPLC analyses of the crude extract of bitter almond indicated that it contains several compounds as shown in Fig.1. An amount of amygdalin in the crude extract is 10.9% based on the external standard curve as determined by HPLC. Although amygdalin is a water-soluble compound, it is more soluble in n-butanol than in water according to the HPLC analysis. In order to achieve an efficient resolution of target compound, the two-phase solvent system of n-butanol-water (1:1, v/v) was first used (Fig. 2a). However, none of the two peaks was found to be amygdalin which was still retained in the column. Then two-phase solvent systems composed of ethyl acetate-water were investigated. Certain volume of n-butanol was gradually added to make ethyl acetate-n-butanol-water at volume ratios of 50:1:50, 10:1:10, 5:1:5, 5:2:5, v/v. (shown in Fig.2 b, c, d, e.). As n-butanol concentration was increased, the partition coefficient of the solute in the upper phase to lower phase increased and the volume ratio of 5:2:5 was considered to be most suitable for the HSCCC run for purification of amygdalin which yields the baseline separation (Fig.2 b.). Then the volume ratio of 5:3:5 system was examined in the test tube, but it showed a long settling time indicating that it would produce a low level of the stationary phase retention in the column. In addition, the volume of the upper phase is 1.5 times that of the lower phase, which is a waste of solvent. Therefore, the volume ratio of 5:2:5 was chosen as the separation. Fig.3 shows the result obtained from 1 g of the crude extract of bitter almond by preparative HSCCC. The second peak was cut and concentrated, yielding 65mg of amygdalin at 97% purity based on the HPLC analysis (Fig.3.).

As shown in Fig. 4, the HPLC analysis of the crude extract of *Agrimonia pilosa* Ledeb shows several compounds where the purity of taxifolin-3-glucoside and hyperoside in the crude extract is 3.1% and 3.3% respectively, based on the HPLC external standard curve. Then two-phase solvent systems composed of ethyl acetate-water were investigated. Methanol was gradually added to make various volume ratios of ethyl acetate-methanol-water at 25:1:25, 10:1:10, and 5:1:5 as shown in Fig.5 a, b, c. It was found that the volume ratio of 25:1:25 was most suitable for the analytical HSCCC run for purification of taxifolin-3-glucoside and quercetin-3- galactoside which gave base line separation (Fig.5 a.). Fig. 6 shows the result obtained from 400 mg of the extract of *Agrimonia pilosa* Ledeb by preparative HSCCC. Peak 1 and peak 2 were cut and concentrated yielding 11 mg of taxifolin-3-glucoside and 8 mg of quercetin-3-galactoside each at 96% purity based on the HPLC analysis.

The structural identification of amygdalin was carried out by MS, ¹H-NMR and ¹³C- NMR spectra as follows: EI-MS (pos. m/z): 458 [M + H]⁺, 325 [diglucoside]⁺, 117[benzene and -CN]. The results were similar to those in reference [11].

Amygdalin: ¹H-NMR (600MHz, CD₃COCD₃) δ: 7.614 (2H, m) and 7.491 (3H,m)—ArH; 5.945 (1H, s, CHCN); 2.815-4.497(12H, sugar-H), 4.497(1H, d, H-1''), 4.432 (1H, d, H-1'), 4.276 (1H, dd, Hz, H-5''), 4.195 (1H, dd, Hz, H-5'), 2.815 (1H, dd, H-6'), 3.711 (3H, m), 3.347 (4H,m). ¹³C-NMR (600MHz CD₃COCD₃) : δ61.59 (C-6''), 69.13 (C-6'), 69.28 (C-7), 70.10 (C-4'), 70.49 (C-4''), 73.67 (C-2'),74.05 (C-2''), 76.40 (C-3', C-5'), 76.73 (C-3'', C-5''),102.51 (C-1'), 103.67 (C-1''), 119.37 (C-8), 128.16 (C-2,C-6), 129.98 (C-3, C-5), 130.93 (C-4), 133.61 (C-1). The results were similar to those in reference [12], and the compound was identified as amygdalin.

The structural identification of taxifolin-3-glucoside and quercetin-3-galactoside was carried out by MS, ^1H -NMR, and ^{13}C -NMR Spectra as follows: EI-MS: m/z 464(M^+), 302 (100), 274, 217, 153, 137; it showed the molecular ion at m/z 464, which is in agreement with the molecular formula $\text{C}_{21}\text{H}_{20}\text{O}_{12}$ of quercetin-3-galactoside [13]. EI-MS: m/z 466(M^+), 304, 276, 137 which is in agreement with the molecular formula $\text{C}_{21}\text{H}_{22}\text{O}_{12}$ of taxifolin-3-glucoside [14].

Quercetin-3-galactoside: ^1H -NMR (500 MHz, DMSO) δ ppm: 5.351 (1H, H-100), 6.191 (1H, H-6), 6.402 (1H, H-8), 6.811 (1H, H-50), 7.533 (1H, H-20), 7.632 (1H, H-60). ^{13}C -NMR (500 MHz, DMSO) δ ppm: 156.305(C-2), 133.502(C-3), 177.411(C-4), 161.210(C-5), 98.702(C-6), 164.102(C-7), 93.604(C-8), 156.302(C-9), 104.104(C-10), 121.101(C-10), 115.212(C-20), 144.810(C-30), 148.403(C-40), 116.003(C-50), 121.903(C-60), 101.905(C-10), 71.306 (C-20), 73.311(C-30), 68.012(C-40), 75.906(C-50), 60.211(C-60) [15,16].

Taxifolin-3-glucoside: ^1H -NMR (500 MHz, DMSO) δ ppm :8.59 (1H, HO-5), 6.61-6.49 (3H, Ar-H), 5.73 (2H, H-8 and H-6), 5.43 (1H, H-2), 4.98 (1H, H-3), 4.7 (1H, H-1"), 4-3 (5H, H of glucoside) [14].

CONCLUSION

In the present study, About a 1 g amount of the crude extract of amygdalin was isolated to yield 65 mg of amygdalin at 97% purity using a two-phase solvent system composed of ethyl acetate- n-butanol- water (5:2:5, v/v) by preparative HSCCC. About a 400 mg amount of the crude extract of *Agrimonia pilosa* Ledeb was isolated to yield 11 mg of taxifolin-3-glucoside and 8 mg of hyperoside each at 96% purity using a two-phase solvent system composed of ethyl acetate- methanol-water (25:1:25, v/v) by preparative HSCCC. Several kinds of two-phase solvent systems, different volume ratios of ethyl acetate- n-butanol- water or ethyl acetate-methanol- water, were tested in the solvent selection process by analytical HSCCC. The result of this study demonstrates that HSCCC is very useful for the preparative separation of amygdalin, taxifolin-3-glucoside and quercetin-3-galactoside from crude plant extracts.
