Abstract

Protein splicing is a precise post-translational process mediated by inteins. Inteins are intervening proteins that cleave themselves from a precursor protein while joining the flanking sequences. Here we report the ¹⁵N, ¹³C, and ¹H chemical shift assignments of the intein from DNA polymerase II of *Pyrococcus abyssi* (*Pab* PolII intein), which has been recombinantly overexpressed and isotopically labeled. The NMR assignments of *Pab* PolII intein are essential for solution structure determination and protein dynamics study.

Keywords

intein; NMR; assignment; hyperthermophile; DNA polymerase II; *Pyrococcus abyssi*

Biological context

Protein splicing is a precise post-translational process in which an in-frame intervening polypeptide, called an intein, is excised out of a precursor protein, while the flanking sequences, termed the N- and C-exteins, are joined together (Paulus 2000). Protein splicing is orchestrated in a precise sequence of bond rearrangements and is self-contained, requiring no cofactors. Protein splicing has been harnessed as a valuable tool in biomedical research and biotechnology (Elleuche and Poeggeler 2010). Although intein structures have been characterized extensively by X-ray crystallography (Saleh and Perler 2006) and NMR methods (Du et al. 2010; Oemig et al. 2009; Johnson et al. 2007; Frutos et al. 2010a; Du et al. 2009; Frutos et al. 2010b), details of the protein splicing mechanism, including the precise mechanistic roles of highly conserved residues or motifs, are still lacking. This is due, in part, to the spontaneous nature of protein splicing, making it difficult to obtaining functional precursors for structural studies. *Pab* PolII intein is present in a hyperthermophilic organism and can yield a functioning precursor inactive at room temperature. Such an intein precursor, the equivalent of an enzyme-substrate complex, would be ideal for NMR studies of intein mechanism. In addition, the *Pab* PolII intein is only the second intein demonstrated to splice with a C-terminal glutamine (Mills et al. 2004). In contrast to *Chiloiridescent virus* (CIV) RNR intein (Amitai et al. 2004), the mutation of the C-terminal glutamine to an asparagine enhances protein splicing by three fold (Mills et al. 2004). As a first step towards carrying out structural and mechanistic studies at atomic resolution using solution NMR, we have determined the backbone and

sidechain resonance assignments of the wild-type *Pab* PolII intein, which contains 185 residues and no homing endonuclease domain.

Methods and Experiments

The *Pab* PolII intein gene cloned into the pETM-44 vector ppC1Q185 expresses a fusion protein with a N-terminal (His)₆ tag and maltose-binding protein (MBP). There is a single proline between the (His)₆-tag and MBP and a linker sequence TPGSLEVLKQGPM between MBP and the intein. Isotopically labeled ([U-¹⁵N] and [U-¹³C; U-¹⁵N] and [~70%-²H; U-¹³C; U-¹⁵N]) proteins were obtained by transforming the plasmid into *E. coli* strain BL21(DE3) and over-expressing the fusion protein in M9 medium. The M9 cultures were incubated at 37 °C until OD₆₀₀ reaches 0.6–0.8 and induced with 1 mM isopropyl-1-thio-β-D-galactopyranoside (IPTG) and incubated for additional 16 hours at 20 °C. Cell lysate was purified by nickel-NTA affinity chromatography to obtain the fusion protein. The inteins were cleaved from the N-terminal affinity domain by incubation with 100 mM dithiothreitol (DTT) at 60 °C for six hours. Affinity chromatography was utilized again to trap the (His)₆-tagged MBP and uncleaved fusion protein, with the *Pab* PolII intein collected in the flow through. The protein was then exchanged into buffer containing 20 mM sodium phosphate, 0.5 mM ethylenediaminetetraacetic acid (EDTA), and 0.05 mM sodium azide in 90% H₂O/10% D₂O or 99.9% D₂O at pH 6.5. The final concentrations of the NMR samples are between 1.2–2.0 mM.

All spectra were acquired at 47 °C on a Bruker 800MHz or 600MHz (¹H) spectrometer each equipped with a cryogenic probe. Spectra were processed with nmrPipe software and analyzed using Sparky (T. D. Goddard and D. G. Kneller, SPARKY 3, University of California, San Francisco, USA). The ¹H chemical shifts were referenced relative to DSS (4,4-dimethyl-4-silapentane-1-sulfonic acid) and the ¹⁵N and ¹³C chemical shifts were referenced indirectly using the frequency ratios between ¹⁵N, ¹³C, and ¹H (¹⁵N/¹H=0.101329118, ¹³C/¹H=0.251449530).

The backbone sequence-specific assignments of ¹H^N, ¹³C^α, ¹³C', and ¹⁵N for the *Pab* PolII intein were obtained using standard triple resonance NMR methods, such as HNCACB, HN(CO)CACB, HNCO, HN(CA)CO, HNCA, and HN(CO)CA, with deuterium decoupling when necessary. Nearly complete backbone assignments were obtained (~97%) with the exception C1, Y172, H173, N174, and Q185. The backbone resonance assignments are illustrated in Fig. 1. Assignments for aliphatic side chains were achieved by using 3D H(CC)(CO)NH, (H)C(CCO)NH, HCCH-TOCSY, ¹⁵N-NOESY and ¹⁵N-TOCSY.

Extents of assignments and data deposition

The *Pab* PolII intein contains 185 amino acid residues. Assignments of backbone resonances ¹H^N, ¹⁵N, ¹³C^α, ¹H^α, and ¹³C' were nearly completely assigned (97%) with the exception of the resonances of C1, Y172, H173, N174, and Q185 and ¹⁵N resonances of seven proline residues P3, P16, P43, P71, P94, P135 and P143. Subsequently, all aliphatic side chain resonances were assigned to 96% complete with the exception of I52 L167, Y172, H173, N174, H184 and Q185. Most ¹³C chemical shifts were derived from ¹³C HCCH-TOCSY of a uniformly ¹³C labeled sample without deuteration. One of the K69 H_ε has a chemical shift of 1.11 ppm and put it as the lowest chemical shift of lysine H_ε protons reported in the BioMagResBank (<http://www.bmr.b.wisc.edu>). This could be due to the ring current effect of the nearby F162 and F165 in 3D structure of intein. The chemical shifts have been deposited in the BioMagResBank under accession number 17418.
