Abstract

A novel diastereoselective synthesis of substituted pyrrolidines has been developed. Asymmetric multi-component reactions of optically active phenyldihydrofuran, *N*-tosyl imino ester and silane reagents in a one-pot operation afforded highly substituted pyrrolidine derivatives diastereoselectively. The reaction is quite efficient and constructed up to three stereogenic centers in a single operation.

Multicomponent reactions (MCRs) that provide functionalized heterocyclic scaffolds in a single operation and in a stereodefined manner are of enormous importance in synthetic organic and medicinal chemistry. Despite the significance and potential of MCRs, there exist only few versatile multicomponent reactions that truly generate diverse molecules with multiple stereocenters.¹ Our development of multicomponent reactions led to syntheses of a variety of substituted tetrahydrofurans, and tetrahydropyrans containing multiple stereocenters.² Recently, we described multicomponent reactions with *N*-tosyl imino ester that provided rapid access to a range of functionalized novel α -amino acids containing cyclic ether templates.³ As depicted in Scheme 1, multicomponent reactions of *N*-tosyl imino ester with optically active phenyl dihydrofuran (**1**) at $-78\text{ }^{\circ}\text{C}$ to $-20\text{ }^{\circ}\text{C}$ in the presence of allyltrimethylsilane as the nucleophile and CH_3CN as the additive provided a single diastereomer **2** in very good yield. Interestingly, in the absence of CH_3CN additive, this multicomponent reaction typically afforded tetrahydrofuran derivative **2** along with varying amount (15-30%) of pyrrolidine derivative **3a** as the byproduct. Presumably, a Lewis acid-catalyzed intramolecular rearrangement led to the formation of pyrrolidine derivative **3**. The presence of CH_3CN additive completely prevented the formation of pyrrolidine derivative **3**. Pyrrolidine rings are inherent to numerous bioactive natural products and medicinal agents.⁴ The biological significance of functionalized pyrrolidines and prolines continues to stimulate interest in their design and synthesis. In this context, a number of practical synthetic methodologies have been developed recently.⁵ In our continuing interest in probing enzyme active sites with designed ligands containing heterocyclic templates,⁶ we sought to optimize the above multicomponent reaction conditions so as to synthesize functionalized pyrrolidine heterocycles in a stereopredictable manner. Herein we report asymmetric multi-component reactions of optically active phenyldihydrofuran, *N*-tosyl

imino ester and silane reagents in a one-pot operation to afford functionalized pyrrolidine and proline derivatives diastereoselectively.

As mentioned, the above multicomponent reaction of *N*-tosyl imino ester,⁷ 5-phenyl dihydrofuran (**1**)^{8,9} and allyltrimethylsilane in the absence of CH₃CN additive provided phenyl tetrahydrofuran **2** along with pyrrolidine derivative **3a** as the byproduct. We anticipated that the formation of pyrrolidine byproduct **3a** evolved from phenyl tetrahydrofuran **2** by a TiCl₄-promoted formation of benzylic carbocation followed by intramolecular ring closure with the sulfonamide. To examine this presumption, phenyltetrahydrofuran **2** was treated with 1.2 equiv of TiCl₄ in CH₂Cl₂ at -78 °C and the resulting mixture was warmed to 23 °C for 2 h. Indeed, phenyl tetrahydrofuran **2** smoothly converted to pyrrolidine derivative **3a** as a single diastereomer in 90% yield. We then optimized the multicomponent reaction conditions to provide pyrrolidine derivative **3a**. Thus, asymmetric multicomponent reactions leading to effective synthesis of various functionalized pyrrolidines were carried out as follow. Optically active phenyldihydrofuran (**1**, 1.2 equiv) and *N*-tosyl imino ester (1 equiv) in CH₂Cl₂ were treated with TiCl₄ (1M soln in CH₂Cl₂, 1.2 equiv) at -78 °C for 1 h. Allyltrimethylsilane (3 equiv) was added, and the resulting mixture was allowed to warm to 23 °C and stirred for 1 h. After this period, the reaction was quenched with saturated aqueous NaHCO₃ solution. Standard workup and flash chromatography over silica provided pyrrolidine derivative **3a** in 72% yield as a single diastereomer (by ¹H and ¹³C NMR analysis). Reduction of **3a** with NaBH₄ in the presence of CaCl₂ in a mixture of EtOH and THF afforded diol **4** in 88% yield. The assignment of stereochemistry of the three new chiral centers of **3a** was made based upon the X-ray structure of **4** in Figure 1 as well as extensive Noesy experiments.¹⁰ Optical purity of compound **4** was determined by its conversion to the corresponding Mosher ester.¹¹ The ¹⁹F-NMR analysis of the Mosher esters established that the optical purity was 87% ee. Compound **3a** was also converted to proline derivative **5** by saponification using aqueous LiOH followed by exposure of the resulting acid to Na-Hg in methanol at reflux.¹² Proline derivative **5** was obtained in 72% yield in a twostep sequence.

We investigated the feasibility of this reaction protocol with a number of nucleophiles and the results are summarized in Table 1. Multicomponent reactions with allyltributylstannane in the presence of 1.2 equiv of TiCl₄ proceeded with excellent diastereoselectivity (*dr* = 99/1, Table 1, entry 2) and good yield. When triethylsilane was used as a nucleophile pyrrolidine derivatives were obtained as a mixture of diastereomers (*dr* = 90/10, Table 1, entry 3). The corresponding reactions with tributyltinhydride also provided pyrrolidine derivative **3b**. However, diastereoselectivity and yield were further reduced (Table 1, entry 4). We then examined a number of enolsilanes and ketene acetals as the nucleophiles. These reactions were considerably sluggish in the presence of 1.2 equiv of TiCl₄. Multicomponent reactions with enolsilane **6a** in the presence of 1.2 equiv of TiCl₄ at -78 °C to 23 °C provided a mixture (~1:1) of tetrahydrofuran and pyrrolidine derivatives. The use of 4.2 equiv of TiCl₄ however, afforded only pyrrolidine derivative **3c** as a single diastereomer in 63% yield (Table 1, entry 5). The corresponding reaction with *tert*-butyl enol ether **6b** also gave a single diastereomer **3d** in excellent yield (Table 1, entry 6). These reactions with ketene acetals **6c** and **6d** also proceeded with excellent diastereoselectivity.

Lewis acid-catalyzed formation of pyrrolidines as well as high degree of diastereoselectivity associated with these reactions can be rationalized based upon the proposed models in Scheme 2. As described previously,³ we presume that reaction of phenyl dihydrofuran and *N*-tosyl imino ester in the presence of TiCl₄ at -78 °C would furnish oxocarbenium ion **7** which minimizes non-bonding interactions in the transition state. Reaction of **7** with allyltrimethylsilane at -78 °C to -20 °C in the presence of CH₃CN would provide tetrahydrofuran **2** as described previously.³ However in the absence of CH₃CN, Lewis acid

activation of tetrahydrofuran would result in a new oxonium ion **8**. The S_N2 nucleophilic attack of sulfonamide nucleophile (NTs) to the LA-activated oxonium ion **8** may account for the observed complete inversion for **3a** and **3c-f** (Table 1, entries 1-2, 5-8). Alternatively, oxonium ion **8** may subsequently lead to a benzylic carbonium ion **9**. Further rotation of the carbon-carbon bond around the benzylic carbonium ion could provide an alternate carbonium ion **10**. An intramolecular S_N1 attack by the NTs is likely to proceed through **9** over **10** to provide **3b** predominantly because of the absence of developing non-bonding interactions between the phenyl ring and the bulky metal alkoxide. The proposed models account for the observed diastereoselectivity with triethylsilane and tributyltinhydride (Table 1, entries 3 and 4) where steric bulk of metal alkoxide is considerably reduced.

In summary, we have developed highly diastereoselective TiCl₄-catalyzed multicomponent coupling reactions to provide functionalized pyrrolidines with multiple stereocenters. The overall process is quite efficient and the protocol has constructed up to three contiguous asymmetric centers in a single operation. Further studies are under investigation in our laboratory.
