Abstract

Synthetically useful rhodium(II) carbenes were obtained from *N*-(1,2,4-triazolyl)-substituted 1,2,3-triazoles and Rh(II) carboxylates. The electron-withdrawing 1,2,4-triazolyl group reveals heretofore unknown reactivity of non-sulfonyl 1,2,3-triazoles, which exhibit reactivity of diazo compounds. The resulting carbenes provide ready asymmetric access to secondary homoaminocyclopropanes (80–95% ee, dr > 20:1) via reactions with olefins and also engage in efficient transannulation reactions with nitriles.

The intrinsic ability of certain electron-deficient triazoles to undergo ring-chain isomerism¹ opens a possibility of using them as latent diazo compounds. We have recently demonstrated that 1-sulfonyl-1,2,3-triazoles **1** can indeed serve as stable and readily available progenitors of *N*-sulfonyl azavinyl carbenes **2** (Scheme 1, top).² Similarly to transition metal carbenes obtained from diazocarbonyl compounds,³ azavinyl carbenes are useful and versatile reactive intermediates. Their generation does not require preparation and handling of diazo compounds, and their electronic and steric properties, and hence reactivity, can be finely tuned by varying the imine functionality at the vicinal carbon atom.

Reactions of carbenes generated from 1,2,3-triazoles are experimentally convenient and, because the concentration of the reactive carbene is low, do not require special precautions in order to avoid side reactions.

Until now, only sulfonyl triazoles have been shown to produce transition metal azavinyl carbenes. We report here a first example of 1,2,3-triazoles **3** designed to undergo Rh(II) catalyzed transformations, and we demonstrate that an electron-deficient heterocycle at the *N*-1 position of the 1,2,3-triazole ring can facilitate its conversion to the carbene species **4** (Scheme 1). This route significantly expands the repertoire of accessible azavinyl carbenes and allows practical access to synthetically useful secondary amines, which are difficult to obtain by other methods.

Ethyl 1,2,4-triazolyl-1,2,3-triazoles **3**⁴ (see Supporting Information for the preparation procedure) were found to readily produce azavinyl carbenes **4** that reacted with olefins. Thus, in the presence of the Rh₂(esp)₂ complex,⁵ styrene was converted to cyclopropane

Supporting Information **Available**: experimental conditions, optimization procedures, NMR and X-ray data. This material is available free of charge via the Internet at <http://pubs.acs.org>.

carboxaldehyde **5a** in 82% isolated yield (*trans/cis* ratio 3:1; Scheme 2). The Rh₂(piv)₄ catalyst provided the product aldehyde with similarly low diastereoselectivity as well as somewhat lower yield (66%). In contrast, the same reaction carried out with Rh₂(*S*-NTTL)₄ catalyst gave **5a** in 84% yield and 80% ee with significantly improved *trans/cis* ratio (**5:5'** > 20:1). The low diastereoselectivity observed in reactions catalyzed by Rh₂(piv)₄ and Rh(esp)₂ suggests that it is not determined solely by the donor-acceptor electronic properties of these carbenes but also by the steric demands of the imine group, as compared to the sulfonyl azavinyl carbenes^{2d} and those derived from diazoacetates.

Other chiral Rh(II) carboxylates were then evaluated in the cyclopropanation reaction (cf. Table S2 of the supporting information section). However, instead of removing the 5-amino-1,2,4-triazolyl group, we carried out the one-pot reduction of the intermediate imine in order to access valuable heterocyclic secondary amine **6a**. Most chiral catalysts showed excellent diastereoselectivity (*dr* > 20:1) compared to 3:1 obtained for Rh₂(esp)₂. As for the enantioselectivity, Rh₂(*S*-NTTL)₄⁶ and Rh₂(*S*-PTAD)₄ emerged as the most promising catalysts after the initial screening, which was performed in 1,2-DCE at 80 °C. Rh₂(*S*-DOSP)₄ and Rh₂(*R*-NTV)₄ provided **6a** as an opposite enantiomer with 38% and 66% *ee*, respectively. Optimization of the reaction conditions revealed that Rh₂(*S*-NTTL)₄ performed better than other catalysts, giving cyclopropane products with a high 95% *ee* (*d.r.* > 20:1; 65 °C in CHCl₃).

Hydrolysis of the intermediate imine confirmed both relative and absolute stereochemistry of the cyclopropane products. These results correlate well with our prior findings for reactions of 1-sulfonyl-1,2,3-triazoles, in which Rh₂(*S*-NTTL)₄ also gave excellent asymmetric induction in chloroform and 1,2-DCE.^{2b,c} It is worth mentioning that performing the reaction at an elevated temperature did not affect its enantio- and diastereoselectivity.

When other alkenes and triazoles **3** were examined in the reaction with Rh₂(*S*-NTTL)₄, excellent diastereoselectivity and good enantioselectivity were a general trend for this type of carbene (Scheme 3).

The only downside of using the Rh₂(*S*-NTTL)₄ catalyst was the increased reaction time (24 h). Electron-rich olefins (4-methoxystyrene and 1,1-diphenylethylene) produced substituted 2-pyrrolines instead of cyclopropanes in good yields.^{2b} Reactions of triazoles **3** with aromatic and aliphatic nitriles provide substituted triazolyimidazoles **7**. These compounds are likely formed via the initial attack of the nitrile nitrogen at the electrophilic carbene center. Screening of several readily available achiral Rh(II) carboxylates and solvents in the reaction of **3a** with benzonitrile revealed that Rh₂(esp)₂ was the most effective catalyst for this transannulation reaction. Although the imidazole product was formed in all of the tested solvents, 1,2-dichloroethane (1,2-DCE) and chloroform (Table S1 of Supporting Information) gave consistently high yields. Interestingly, the lowest temperature at which reaction occurs is 65 °C. However, it is unclear which particular step requires elevated temperature: 1,2,3-triazole ring opening, the formation of Rh-carbene complex, or the addition of a nitrile. Slightly higher temperatures resulted in shorter reaction times and comparable yields.

At 85 °C, both aliphatic and aromatic nitriles produced imidazoles **7** in good yield (Scheme 4). Despite the multiple attempts to react 4-alkyl (*R*¹ = *t*-Bu, *n*-C₆H₁₃, CH₃OCH₂-) substituted 1,2,3-triazoles with nitriles, we were unable to isolate the corresponding imidazoles in synthetically useful yields. The failure of this reaction is most likely due to the β-hydride shift of the carbene intermediate. Rather surprisingly, the adduct of *p*-

trifluoromethyl phenylacetylene was also found to be a poor carbene precursor for the transannulation reaction.

The relative reactivity of new triazolyl-triazoles **3** was compared with 1-sulfonyl-1,2,3-triazoles in a competition experiment, wherein sulfonyl triazole **8** (1 equiv), triazole **3a** (1 equiv), and styrene (1 equiv) were reacted in chloroform in the presence of 1 mol % of $\text{Rh}_2(\text{S-NTTL})_4$ at 70 °C. After 90 min, full consumption of styrene was observed, and the ratio of the corresponding cyclopropanes **9** and **6a'** was 3:1, indicating that the *N*-sulfonyl triazole **8** reacted with styrene more readily than triazole **3a**. An identical experiment performed at ambient temperature exhibited a similar trend (after 24 h, 10% of styrene was consumed, and **9:6a'** ratio was 3:1). Another control reaction of sulfonyl triazole with 1 equiv of styrene at ambient temperature demonstrated slightly faster consumption of styrene (15% after 24 hours). These results point to the generally lower reactivity of triazolyl triazoles **3a** compared to *N*-sulfonyl triazoles such as **8** and do not support the notion of possible catalyst deactivation by **3a** via the coordination of the nitrogen atoms to the Rh center.⁷

In summary, a new family of azavinyl carbenes obtained from 1,2,3-triazoles containing a carbon substituent at the *N*-1 position is now available. These species display high thermal stability, excellent reactivity, and high chemo- and stereoselectivity in reactions with olefins and nitriles. These *N*-(1,2,4-triazolyl) azavinyl carbenes are versatile reactive intermediates that provide access to highly substituted imidazoles and chiral cyclopropanes containing complex heterocyclic secondary amines.
