Abstract

This report discloses a novel concise synthesis of a series of 3-hydroxypyrazoles **5** via a tandem Ugi/debenzylation /hydrazine-mediated cyclization sequence. Herein, *n*-butyl isocyanide **4b** was utilized as an alternative to classical convertible isocyanides enabling high yielding hydrazine-mediated cyclization. Taken together, a novel class of 3-hydroxypyrazoles **5a–5i** was synthesized with potential to be of interest in future library enrichment strategies.

Keywords

Multicomponent reaction; Ugi reaction; 3-hydroxypyrazole; hydrazine-mediated cyclization

In spite of scarcity in nature,¹ the pyrazole scaffold has been significantly studied mainly due to the discovery of interesting properties exhibited by a great number of its derivatives. Pyrazole, a five-membered heterocycle containing two adjacent nitrogen atoms, is a motif found in a number of small molecules that possess a broad spectrum of pharmaceutical activities.² Particularly noteworthy is celecoxib, containing a 1-arylpyrazole motif which is a selective cyclooxygenase-2 (COX-2) inhibitor for the treatment of a plethora of indications that include osteoarthritis, rheumatoid arthritis, acute pain and others.³ As a consequence, a variety of methodologies to develop pyrazole derivatives have been intensively explored in the past decade.⁴

Multi-component reactions (MCRs) are powerful transformations in which three or more starting materials are incorporated in a one-pot fashion to produce highly functionalized products. Isocyanide-based multicomponent reactions (IMCRs) are of particular interest thanks in part to the large number of commercially available starting materials and wide range of readily accessible pharmacologically relevant scaffolds.⁵ The most well-known IMCR, the Ugi reaction, is carried out through reaction of an amine, carbonyl compound, carboxylic acid, and isocyanide, which undergo a condensation step to afford the corresponding functionalized α -acylamino amide.⁶ The usefulness of such a process as a powerful diversity generating step has been demonstrated by numerous applications in the synthesis of potential drug-like libraries of small molecules.^{5c, 7} Indeed recently, we have

successfully developed a concise synthesis of 2,4,5-trisubstituted oxazoles via a tandem Ugi/Robinson-Gabriel sequence.⁸ Of particular relevance to this article are the extensive studies performed by Krasavin et al. who often employs hydrazines as the amine equivalent to subsequently generate new molecular diversity.⁹ Herein we would like to report a novel hydrazine-mediated cyclization of the Ugi condensation product that affords unique 3-hydroxypyrazoles **5** via a tandem Ugi/debenzylation/hydrazine-mediated cyclization sequence, Scheme 1.

Initial optimization studies focused on 4-*tert*-butyl cyclohexen-1-yl isocyanide **4a**, employed as a convertible isocyanide to increase the acid catalyzed electrophilicity of the isocyanide derived amide carbonyl which in turn was expected to promote the key cyclization step.¹⁰ Thus Ugi product **6a** was initially prepared (MeOH, rt, 36h, 43%) utilizing 2,4-dimethoxybenzylamine **1**,¹¹ 4-bromobenzoic acid **2a**, phenylglyoxal **3a** and 4-*tert*-butyl cyclohexen-1-yl isocyanide **4a**, Scheme 2.

Subsequent treatment of **6a** with hydrazine mono-hydrochloride in ethanol (accelerated via microwave irradiation) successfully afforded the 3-hydroxypyrazole **7a** in 45% isolated yield. At this stage the unaccounted for mass balance seemed to be composed of several unidentified side products. Removal of the 2,4-dimethoxybenzyl moiety from **7a** was successfully carried out at 80°C for 10 min under microwave irradiation in 10% TFA/DCE solution to afford the corresponding 3-hydroxypyrazole **5a** (82% isolated yield) which was characterized by X-ray crystallographic analysis, Figure 1a. Interestingly, an intra-molecular hydrogen bond was observed between the 3-hydroxyl group and the carboxamide carbonyl of **5a**, Figure 1b.

Not satisfied with the first two steps of the sequence (both < 50%), attempts to further optimize yields were undertaken through replacement of **4a** with *n*-butyl isocyanide **4b**, and an alteration in the order of the reaction sequence Scheme 3.¹² Consequently, the Ugi product **6b** was prepared in improved yields (**6a**, 43%, **6b**, 57%) and de-benzylation was conducted prior to pyrazole formation to afford the *N*-acyl- α -aminoketone **8**, Scheme 3. Without further purification, *N*-acyl- α -aminoketone **8** was subjected to hydrazine-mediated cyclization conditions to give the desired 3-hydroxypyrazole **5a** with improved conversion (56% isolated yield in two steps).¹³

With satisfactory conditions in place, a small array of 3-hydroxypyrazoles was thus synthesized with diversity being generated through the utilization of various carboxylic acids **2** and arylglyoxals **3** to establish the scope of the methodology. Indeed, the new tandem Ugi/debenzylation/hydrazine-mediated cyclization sequence furnished Ugi products and 3-hydroxypyrazoles with yields ranging from 44–58% and 38–62%, respectively, Figure 2.

In summary, a series of novel 3-hydroxypyrazoles **5a–5i** were synthesized in three steps employing a tandem Ugi/debenzylation/hydrazine-mediated cyclization sequence and *n*-Butyl isocyanide **4b** was an effective replacement for 4-*tert*-butyl cyclohexen-1-yl isocyanide **4a** for the hydrazine-mediated cyclization step. The novel class of 3-hydroxypyrazoles are fully expected to be of high interest in medicinal chemistry groups, in particular those involved in kinase inhibitor design.
