A 41-year-old female with a history of ventricular septal defect repair presented to the emergency department with complaints of intermittent palpitations. On admission, she was haemodynamically stable. A standard 12-lead ECG done in the emergency room is shown in

Fig. 1. What is the diagnosis? What is the critical physical examination finding you should look for in this patient?

Answer

You will find the answer elsewhere in this issue (Fig. 2).
