Abstract

In this work, it is shown that novel aqueous two-phase systems can be formed by the combination of acetonitrile and polysaccharides, namely dextran. Several ternary phase diagrams were determined at 25 °C for the systems composed of water + acetonitrile + dextran. The effect of the dextran molecular weight (6,000, 40,000 and 100,000 g.mol⁻¹) was ascertained toward their ability to undergo liquid-liquid demixing. An increase in the dextran molecular weight favors the phase separation. Furthermore, the effect of temperature (25, 35 and 45 °C) was evaluated for the system constituted by the dextran of higher molecular weight. Lower temperatures are favorable for phase separation since lower amounts of dextran and acetonitrile are required for the creation of aqueous two-phase systems. In general, acetonitrile is enriched in the top phase while dextran is majorly concentrated in the bottom phase. The applicability of this new type of two-phase systems as liquid-liquid extraction approaches was also evaluated by the study of the partition behavior of a well-known antioxidant – vanillin - and used here as a model biomolecule. The optimized conditions led to an extraction efficiency of vanillin of 95% at the acetonitrile-rich phase.

Keywords

aqueous two-phase system; acetonitrile; dextran; vanillin; extraction

1. Introduction

Aqueous two-phase systems (ATPS) are widely applied in biotechnology for the isolation and purification of enzymes such as lipase [1-3], antioxidants, namely rutin [4] and gallic acid [5], alkaloids, such as theobromine, theophylline, nicotine and caffeine [6], antibiotics, for instance tetracycline [7,8], and antibodies [9,10]. The main advantages of ATPS rely on their scale-up possibility, on the rapid mass transfer and phase equilibrium, possibility of a continuous processing, low energy requirements, among others [11].

ATPS are usually formed by mixing two polymers in aqueous media, for instance polyethylene glycol (PEG) and dextran [12,13] or PEG and maltodextrin [14], or by one polymer and one salt, such as PEG and phosphate-based salts [15-17] or PEG and citrate-based salts [18,19]. However, some other pairs of phase-forming components can be used in the creation of alternative ATPS, such as alcohol + salt [20], ionic liquid + salt [21-23], ionic liquid + PEG [24,25] and ionic liquid + carbohydrate [26].

Previously we have also demonstrated that alternative aqueous biphasic systems can be created by combining acetonitrile and carbohydrates (monosaccharides and disaccharides) [27] as well as with polyols [28]. In this context, we attempted now the formation of novel ATPS formed by acetonitrile and polysaccharides, namely dextran.

Dextran is a water soluble biopolymer produced by a variety of lactic acid bacteria, such as *Leuconostoc* sp., and which presents two valuable properties: biodegradability and biocompatibility [29]. The chemical structure of dextran is predominantly formed by 95% of linear α -(1 $\rightarrow$ 6) linkages as the main backbone and 5% of α -(1 $\rightarrow$ 3) branch linkages [30]. This homopolymer of glucose has several targeted industrial applications, varying from food, cosmetic, and pharmaceutical to oil drilling industries [31].

Acetonitrile (CH_3CN) – ACN - is an interesting solvent due to its properties; it is aprotic and strongly polar and is obtained as a by-product from the manufacture of acrylonitrile [32]. ACN is widely used by industry in the production of perfumes, rubber products, pesticides or pharmaceuticals [33], and in chromatography processes as a mobile phase in high performance liquid chromatography – HPLC [34,35]. This solvent is miscible with water in all proportions [36] and its molecules are unable to strongly associate with themselves leaving a hydrogen-bond network formed by water [37,38].

The aim of the present work is to study novel aqueous two-phase systems based on acetonitrile and several dextrans of different molecular weights. The ternary phase diagrams were determined at 25 °C and the effect of the polysaccharide molecular weight was evaluated. Moreover, the effect of temperature (25, 35 and 45 °) through the phase diagrams behavior was also addressed for the ATPS constituted by the dextran of higher molecular weight. These systems were also ascertained on what regards their applicability on extraction routes, and in particular on the extraction of a well-known antioxidant, vanillin (4-hydroxy-3-methoxybenzaldehyde). Vanillin is the major flavor constituent of natural vanilla - *Vanilla planifolia*, extracted at a rate of 12,000 ton/year [39]. Vanillin is widely used as a flavoring material in confectionery, food products, beverages, perfumes and in pharmaceutical preparations [40]. Natural vanillin costs between 1,200 and 4,000 USD/kg, while synthetic vanillin costs around 15 USD/kg [41]. However, the chemical process usually leads to a low quality vanillin that further requires a sensitive extraction and purification procedure [42], and for which ATPS can be foreseen as an alternative approach.

2. Material and Methods

2.1. Materials

The ATPS studied in this work were formed by dextran from *Leuconostoc* spp. ($M_w = 100.000 \text{ g.mol}^{-1}$ – Dx-100; $40.000 \text{ g.mol}^{-1}$ – Dx-40; and 6.000 g.mol^{-1} – Dx-6) and acetonitrile. Dextran and acetonitrile (purity of 99.9 wt%), as well as vanillin (> 99 wt% pure) were purchased from Sigma-Aldrich. The chemical structures of the phase-forming components of the ATPS studied and of the target biomolecule used in the partitioning experiments are shown in Figure 1. Distilled and deionized water was used in all experiments.

2.2. Phase diagrams and tie-lines

The ternary phase diagrams for water, acetonitrile and the different molecular weight dextran were determined at 25, 35 and 45 (± 1) °C in atmospheric pressure by the cloud point titration method [43]. Pure acetonitrile (since it is water soluble in the whole composition range and no precipitation effects were observed during the determination of the liquid-liquid saturation curves) and a solution of dextran (Dx-100, Dx-40 and Dx-6) at 20 wt% (a concentration close and below their saturation limit in water at room temperature) was previously prepared and used for the determination of the binodal curves. Repetitive drop-wise addition of pure acetonitrile to the aqueous solution of dextran was carried out until the detection of a cloudy solution, followed by the drop-wise addition of ultra-pure water until the inspection of a monophasic region (clear and limpid solution). These additions were carried out under continuous stirring and the saturation curves were determined gravimetrically within $\pm 10^{-4}$ g.

The tie-lines (TLs) were obtained through a gravimetric method originally described by Merchuk et al. [44]. Several mixtures at the biphasic region of the ternary systems were prepared (total of 5 g), vigorously stirred, and allowed to reach equilibrium and phase separation, for a minimum of 18 h at 25, 35 and 45 (± 1) °C. The temperature was maintained by means of a temperature-controlled water-bath. Initially, aqueous solutions of each dextran were prepared followed by the addition of pure ACN to reach a specific mixture composition. After the equilibration step, the top and bottom phases were carefully separated and weighted within $\pm 10^{-5}$ g. Each individual TL was determined by the application of the lever-arm rule, which describes the relationship between the weight of the top phase and the overall system weight and composition. For that purpose, the binodal curves were correlated using Eq. 1,

$$Y = A \exp \left\{ \left(B \times X^{0.5} - \left(C \times X^3 \right) \right) \right\} \quad (1)$$

where Y and X are the acetonitrile and dextran weight fraction percentages, respectively, and A , B and C are constant values obtained by the fitting of the experimental saturation curve data.

The determination of the TLs, describing the composition of Y and X at the top (T) and bottom phases (B) - Y_T , Y_B , X_T and X_B - was then accomplished by solving a system of four

equations derived from Eq. 1 [43,44]. The respective tie-line lengths (TLLs) were determined through the application of Eq. 2,

$$TLL = \sqrt{(X_T - X_B)^2 + (Y_T - Y_B)^2} \quad (2)$$

2.3. Partitioning of vanillin

Dextran and an aqueous solution of vanillin (0.1 g.L^{-1}) were initially mixed, and after the complete homogenization, acetonitrile was added to reach the chosen mixture composition. Each ATPS (total of 5 g) was prepared in glass tubes. After the complete mixing of all components, for a given mixture composition, each tube was immersed in a thermostatic water bath from 5 to $45 (\pm 1)^\circ \text{C}$ for at least 18 h. After equilibration, both phases were separated for the quantification of vanillin. At least three independent replicates were made and the average partition coefficients and associated standard deviations were therefore determined.

The concentration of vanillin at each aqueous phase was quantified through UV-spectroscopy, using a Varian Cary 50 Bio UV-Vis spectrophotometer, and at a wavelength of 280 nm using a calibration curve previously established. At the concentration of vanillin used, dilutions in the order of 1:50 (v:v) were carried out in distilled water. At these dilutions there are no interferences by the phase-forming components at 280 nm in the quantification of vanillin. Therefore, no blanks were needed for the vanillin quantification at the dilutions carried out.

The partition coefficient of vanillin was determined taking into account the concentration of the antioxidant in each phase and according to,

$$K_{Van} = \frac{C_{Van,T}}{C_{Van,B}} \quad (3)$$

where K_{van} is the partition coefficient of vanillin, C represents the vanillin concentration, and the subscripts T and B symbolize the top (acetonitrile-rich) and bottom (dextran-rich) phases, respectively.

The percentage extraction efficiencies of vanillin, $EE_{van}\%$, were defined as the percentage ratio between the amount of vanillin in the acetonitrile-rich phase and that in the total mixture, according to:

$$EE_{van}\% = \frac{w_{van,T}}{w_{van,T} + w_{van,B}} \times 100 \quad (4)$$

where $w_{van,T}$ and $w_{van,B}$ are the weight of vanillin in the acetonitrile-rich (top) phase and in the dextran-rich (bottom) phases, respectively.

3. Results and Discussion

The effect of different molecular weights of dextran towards the phase separation in acetonitrile-aqueous solutions was firstly addressed through the determination of the respective phase diagrams at 25 °C. Then, the impact of temperature was evaluated with a fixed ATPS and for which the respective phase diagrams were determined at 25, 35 and 45 °C. Further, the potentiality of these systems for the extraction of biomolecules, using vanillin as a model antioxidant, was assessed. The effects of the dextran and ACN concentrations as well as of temperature were also evaluated in what concerns the vanillin partitioning.

3.1. Ternary Phase Diagrams

Three high molecular weight dextrans (Dx-100, Dx-40 and Dx-6) were used in combination with acetonitrile in aqueous media, and the respective phase diagrams were determined at 25°C and atmospheric pressure. The binodal curves experimentally determined are depicted in Figure 2 in molality units (mole of ACN or mole of dextran *per* kg of solvent) for an enhanced understanding on the impact of the distinct dextrans through the formation of ATPS. The respective experimental weight fraction data are provided in the Supporting Information.

The analysis of Figure 2 reveals a strong displacement of the binodal curves towards the origin in the following order: Dx-6 > Dx-40 > Dx-100. In general, the higher the molecular weight of the polysaccharide the more able it is to form two aqueous rich phases with acetonitrile. These results corroborate those found by Lima and co-workers [27] where higher molecular weight carbohydrates, namely monosaccharides and disaccharides, result in a higher ability for phase separation. The increase of the molecular weight of dextran leads to an increase on the number of hydroxyl groups *per* mole of biopolymer. Indeed, and as previously discussed by Freire and co-workers [26], the number of hydroxyl groups present in carbohydrates as phase-forming components of ATPS is directly associated with its capability to hydrogen-bond with water and, therefore, to act as sugaring-out species. In the same context, Lima and co-workers [28] also demonstrated that polyols with more hydroxyl groups are more able to form ATPS with acetonitrile. In addition, as the molecular weight of the polysaccharide increases, the binodal curves shift to lower dextran and ACN concentrations. This is a main result of the decreasing solubility of the dextran in water with an increase in its molecular weight. Therefore, species with low affinity for water are also more able to be phase separated and to form an ATPS. This tendency is in agreement with other experimental results for ATPS composed of polymers and ionic liquids [45], polymers and salts [46] or dextran and a polymer [47].

Figure 3 shows a general comparison between the strongest sugaring-out agents previously reported (a disaccharide and a polyol) [29,30], and the dextran with the highest molecular weight determined here, on their ability to form ATPS with acetonitrile. In fact, it is clearly seen that polysaccharides perform as better sugaring-out agents when compared with carbohydrates of lower molecular weight and polyols. In summary, lower amounts of dextran are required to induce the liquid-liquid demixing when compared to disaccharides

and polyols and which can be foreseen as a major advantage towards the sustainability concept.

Finally, the effect of temperature on the phase diagrams behavior was evaluated with the ATPS formed by Dx-100 and ACN. The binodal curves obtained at 25, 35 and 45 °C are presented in Figure 4. The binodal curves reveal that an increase in temperature decreases the immiscibility region. In general, lower temperatures are favorable for phase-separation since lower amounts of ACN and dextran are required. Dextran is more water-soluble at higher temperatures and thus it is more difficult to create an ATPS. The pattern observed is in close agreement with that observed in dextran-polymer [48].and in ionic-liquid-carbohydrate ATPS [49].

All experimental binodal data were fitted using the empirical relationship described by Eq. 1. The fitted parameters A , B and C (estimated by least-squares regression), and the corresponding standard deviations and regression coefficients are presented in Table 1. As can be seen by the gathered correlation coefficients, Eq. 1 provides an accurate description of the experimental saturation curves. To complete the phase diagrams, several TLs and respective TLLs were additionally calculated and their values are reported in Table 2.

3.2. Partitioning of vanillin

In order to evaluate the potential of the studied ATPS to be applied as extractive systems, vanillin was thorough used. The partition coefficients and the extraction efficiencies of vanillin at the acetonitrile-rich phase were determined at different compositions and at several temperatures.

Contrarily to more conventional ATPS composed of polymer-salt or polymer-polymer combinations, it should be remarked that the dextran-ACN-based ATPS proposed here allow the simple recovery of the phase-forming components since ACN and water are volatile and the polysaccharide can be easily recovered after an evaporation step. This opportunity certainly leads to further investigations on these systems as alternative extraction/separation techniques when foreseeing more sustainable processes with a combined recovery and reuse of the ATPS phase-forming components.

3.2.1. Influence of the dextran molecular weight—Two-phase systems composed of 15 wt% of dextran and 30 wt% of ACN, and for the 3 different molecular weights dextran (Dx-6; Dx-40 and Dx-100), were used to study the partitioning behavior of vanillin. All these results were obtained at 25°C. The partition coefficient (K_{van}) and extraction efficiency of vanillin ($EE_{van}\%$) for the top (acetonitrile-rich) phase are shown in Figure 5 and the corresponding numeric values are reported in the Supporting Information. Figure 5 allows the inspection through the influence of the dextran molecular weight on the vanillin partitioning among the two phases.

For Dx-6 and Dx-40, vanillin displays a similar partitioning behavior between the coexisting phases ($K_{van} \approx 1.7$ -1.8). Nevertheless, the use of Dx-100 leads to a preferentially partitioning of vanillin for the ACN-rich phase ($K_{van} > 3.0$). In general, an increase on the molecular weight of dextran induces an increase on the partition coefficient of vanillin,

particularly seen with Dx-100. This effect can be explained by a volume exclusion model [50], where the intermolecular spaces in the dextran-rich phase are reduced with the increase on the molecular weight, and consequently, vanillin migrates for the top phase (ACN-rich phase). Other authors also observed the volume exclusion effect using polymers as polyethylene glycol in the partition behavior of bromelin [51] and protease [52]. However, and as previously shown by us [29,30], this increase on the partition coefficients for the ACN-rich phase can be also a result of a sugaring-out phenomenon of the polysaccharide over the target biomolecule.

The extraction efficiency of vanillin in the ACN-rich phase ranges between 77 and 88% with higher values achieved with Dex-100. In summary, the highest partition coefficient and recovery of vanillin in the ACN-rich phase was observed with the system composed of Dx-100, the higher molecular weight polysaccharide investigated.

3.2.2. Influence of the dextran/acetonitrile concentrations—To initially evaluate the effect of the dextran concentration through the vanillin partitioning, a series of ATPS containing variable concentrations of Dex-100 (from 15-20 wt%) at fixed amounts of ACN (25, 30 and 35 wt%) were prepared. The results obtained are depicted in Figure 6 and in the Supporting Information.

Although the differences are not very significant, in general, an increase in the dextran concentration leads to a decrease in the partition coefficients and extraction efficiencies of vanillin, been this effect more pronounced with the higher ACN content. Therefore, lower amounts of dextran are enough to lead to high extraction efficiencies and which represent a decrease on the economic costs associated to these ATPS. The recovery values of vanillin at the ACN-rich phase range between 79 and 95% and are vely close to those found by us (98-99%) using ATPS constituted by alcohols and strong salting-out species and high charge density potassium phosphate salts [20].

At all concentrations of dextran it is observed a maximum value either on the partition coefficients or on the extraction efficiencies that occurs at 30 wt% of ACN. It seems thus that there is a multibalanced phenomenon governing the partitioning trend of vanillin.

3.2.3. Influence of temperature—In the previous sections it was demonstrated that by choosing a high molecular weight dextran (Dx-100) at a concentration ranging between 15-20 wt%, vanillin can be effectively separated and concentrated into the top phase. Therefore, the effect of temperature was also evaluated at temperatures varying between 5 and 45 °C, for the common mixture composition of 30 wt% of ACN + 18 wt% of Dx-100. The results obtained are depicted in Figure 7 whereas the respective values are presented in the Supporting Information.

At all temperatures, vanillin preferentially migrates for the top phase ($1 < K_{\text{van}} < 11$). However, these values are somewhat lower than those observed with ATPS composed of ionic liquids + potassium phosphate ($7 < K_{\text{van}} < 50$) [53] and of acetonitrile + polyols ($7 < K_{\text{van}} < 67$) [28]. However, the partition coefficients obtained in this work are similar to those

reported by Lima and co-workers [27] using ATPS formed by acetonitrile and carbohydrates ($3 < K_{\text{van}} < 10$).

The results obtained indicate that temperature influences the vanillin partitioning. This effect can be divided into two parts: (i) between 5 and 25 °C in which the K_{van} reaches the maximum value (11.26); (ii) and between 25 and 45 °C in which the partition coefficient of vanillin decreases with an increase in temperature. Similarly to the results on the vanillin partitioning in ionic-liquid-salt ATPS [53] it was also observed here a maximum value in the partition coefficient as a function of temperature. This maximum as a function of temperature suggests that the partition phenomenon is driven by opposite effects resulting from enthalpic and entropic contributions as previously discussed [53]. The extraction efficiency of vanillin for all system ranges between 70 and 95 % and a similar trend with temperature is observed when compared with the partition coefficients.

4. Conclusions

In this work, novel aqueous two-phase systems based on acetonitrile and dextran were proposed. The binodal curves, which define the mono- and biphasic regimes, were determined at 25°C and at atmospheric pressure for three dextran polysaccharides of different molecular weight, namely 6,000, 40,000 and 100,000 mol.kg⁻¹. In general, the higher the molecular weight of dextran, the higher is the ability of the system to undergo phase separation. The effect of temperature was also evaluated. Higher temperatures are not favorable for inducing the formation of ATPS. Lower amounts of dextran and acetonitrile are required to form an ATPS at lower temperatures.

The novel ATPS were also evaluated in what concerns their potential for extraction purposes. Vanillin was used as a model antioxidant or bioactive substance. In all situations, vanillin preferentially migrates for the acetonitrile-rich phase. The higher partition coefficients and extraction efficiencies of vanillin at the acetonitrile-rich phase were observed with the dextran with the higher molecular weight (Dx-100) and at 25°C. The highest value of K_{van} (11.3) and $EE_{\text{van}}\%$ (95%) was found using an ATPS composed of 18 wt% of Dx-100 and 30 wt% of acetonitrile at 25°C.

Figure 1. Chemical structures of the phase-forming components used in the ATPS formation and of the biomolecule used as a partitioning solute: (a) dextran; (b) acetonitrile; (c) vanillin.

Figure 2. Binodal curves (in molality) for the ternary systems composed of dextran + acetonitrile + water at 25 °C and atmospheric pressure: (♦) Dx-100; (●) Dx-40; (■) Dx-6.

Figure 3. Binodal curves (in molality) for the ternary systems composed of acetonitrile + carbohydrates at 25 °C and atmospheric pressure: (♦) dextran; (●) maltitol [28]; (■) maltose [27].

Figure 4.

Binodal curves (in molality) for the ternary systems composed of Dx-100 + acetonitrile + water at atmospheric pressure: (♦) 25°C; (●) 35°C; (■) 45°C.

Figure 5.

Effect of the dextran molecular weight on the vanillin partitioning at 25 °C for the system composed of dextran (15 wt%) + acetonitrile (30 wt%) for the acetonitrile-rich phase. Bars – extraction efficiency ($EE_{\text{van}}\%$); symbols – partition coefficient (K_{van}).

Figure 6.

Effect of the dextran concentration on the vanillin partitioning (Bars: extraction efficiency - $EE_{van}\%$; symbols: partition coefficient - K_{van}) for the acetonitrile-rich phase at 25 °C for the system composed of Dx-100 (15–20wt%) + fixed concentrations of acetonitrile: ACN at 35 wt% (blue bars and ▲); ACN at 30 wt% (green bars and ■); ACN at 25 wt% (yellow bars and ●).

Figure 7.

Effect of the acetonitrile concentration on the vanillin partitioning for the acetonitrile-rich phase at 25 °C for the system composed of ACN (25-35 wt%) + fixed concentrations of dextran: (a) dextran at 15 wt%; (b) dextran at 17 wt%; (c) dextran at 18 wt%; (d) dextran at 20 wt. Bars – extraction efficiency (EE_{van}); symbols – partition coefficient (K_{van}).

Figure 8.

Effect of temperature on the vanillin partitioning for the acetonitrile-rich phase for the system composed of Dx-100 (18 wt%) + acetonitrile (30 wt%). Bars – extraction efficiencies ($EE_{\text{van}} \%$); symbols – partition coefficients (K_{van}).

Table 1

Correlation parameters used to describe the experimental binodal data by Eq. 1 and respective standard deviations (σ) and correlation coefficients (R^2).

Temperature	Dextran	$A \pm \sigma$	$B \pm \sigma$	$C \pm \sigma$	R^2
25 °C	6.000 g.mol ⁻¹	77.11 ± 10.89	-0.47 ± 0.05	3.97E ⁻¹⁵ ± 4.24E ⁻⁵	0.9722
	40.000 g.mol ⁻¹	38.12 ± 1.20	-0.24 ± 0.01	1.61E ⁻¹³ ± 2.09E ⁻⁵	0.9851
	100.000 g.mol ⁻¹	33.75 ± 0.53	-0.20 ± 0.01	2.03E ⁻⁵ ± 6.62E ⁻⁶	0.9912
35 °C	100.000 g.mol ⁻¹	94.45 ± 2.10	-0.28 ± 0.01	1.08E ⁻⁴ ± 5.25E ⁻⁶	0.9993
45 °C	100.000 g.mol ⁻¹	135.80 ± 3.44	-0.39 ± 0.01	1.33E ⁻¹³ ± 1.11E ⁻⁵	0.9958

Table 2

Mass fraction composition for the TLs and respective TLLs, at the top (T) and bottom (B) phases, and initial biphasic composition of the mixture (M), for the systems composed of acetonitrile (Y) and dextran (X) at 25-45°C.

Weight fraction composition / wt %								
Acetonitrile + Dextran + water systems								
Temperature	Dextran	Y_M	X_M	Y_T	X_T	Y_B	X_B	TLL
25 °C	6.000 g.mol ⁻¹	29.92	10.14	46.56	1.12	8.26	21.88	53.42
		30.03	12.99	55.70	0.46	7.75	23.92	53.64
	40.000 g.mol ⁻¹	20.35	15.41	31.82	0.53	10.25	28.51	35.33
		20.00	10.03	29.12	1.19	14.58	15.28	20.24
	100.000 g.mol ⁻¹	20.13	15.88	33.37	0.00	4.16	35.57	45.87
		22.50	10.00	31.08	0.17	5.54	32.06	40.85
	100.000 g.mol ⁻¹	29.88	17.95	61.99	2.21	0.49	32.35	68.49
		30.98	15.53	60.43	2.48	1.72	28.50	64.22
45 °C	100.000 g.mol ⁻¹	30.02	17.98	39.78	9.99	14.18	32.45	33.31
		39.54	14.86	51.34	6.02	13.16	34.64	47.72
