The book forms a sort of sandwich, with brief sections entitled "The heart, basic principles" and "The vascular system, basic principles" flanking the central 20 chapters on congenital heart disease by Anderson and Becker. These authors expound the subject in their usual elegant manner throughout, and their detailed descriptions will be valued for reference by surgeons and pathologists. The large and beautiful specimens illustrated now rarely present to the histopathologist, who mainly sees cases terminated following prenatal diagnosis in the second trimester or from deaths after reconstructive surgery. Anderson and Becker may be correct in their belief that interpretation of malformed hearts need owe nothing to concepts of embryogenesis. However, the paucity of links to embryonic development, genetic associations, or the practical problems of early fetal or post-surgical studies must render their descriptive analysis of anatomical minutiae a somewhat sterile exercise to many practising pathologists.

To this reviewer, chapters on basic principles forming the outside of the sandwich are intellectually tastier than the filling.

JS WIGGLESWORTH

Primary Bone Tumors and Tumorous Conditions in Children. Pathologic and Radiologic Diagnosis. C-P Adler, K Kozlowski. (Pp 267; 381 illustrations; DM 418.) Springer. 1993. ISBN 3-540-19731-1.

This book, as its name would suggest, concentrates on bone neoplasms in children and as such is an important rarity. It is divided into four unequal parts; the first, entitled "Introduction", is eight pages long and in two sections. The first section puts into perspective the role of various specialist doctors in the recognition, diagnosis and management of this group of neoplasms, and the second section gives some epidemiological data. These data are difficult to assimilate at first, but once the methods of presentation have been understood this section contains some interesting pieces of information.

The second part of the book, "Bone tumours", is 94 pages long and comprises a series of two-page descriptions of each bone tumour. Each contains epidemiological, radiographic, and pathological data with, in some cases, radiographs and macro- and microscopic photographs. The macroscopic and microscopic descriptions are rudimentary and the photographs unhelpful. Some unusual components are included such as osteochondroma (exostosis) under "Tumours of cartilaginous origin", fibroblastic periosteal reaction and fibrous dysplasia under "Tumours of fibrous tissue origin", histiocytosis X under "Tumours of marrow origin", and massive osteolysis under "Tumours of vascular origin". There are some omissions; for example, where was the description of PNET?

The third part, "Tumour-like bone lesions", is 15 pages long and is laid out similarly. Although only six conditions are described, the same criticisms of classification apply as to the previous section. For example, is myositis ossificans really a tumour-like lesion of bone?

The fourth and largest part is entitled "Radiographic approach to the diagnosis of primary bone tumours" and is 142 pages

long. This is the most interesting part of the book, especially for the histopathologist, in that a list is given of the most common tumours of childhood for each bone. The section is divided up by bone rather than tumour; the sections on the ribs, the sacrum, and the femoral neck give some particularly fascinating insights into the skeletal distribution of these tumours in the bones of children.

As an overview of skeletal neoplasms in childhood this book has a lot to recommend it. Unfortunately, because of the way in which it is laid out, much of the information is often difficult to access. Furthermore, the pathological descriptions are scanty and, as pointed out by the authors in the foreword, are not for specialists in histopathology. I cannot therefore recommend this book for the readers of this journal. There are better books on the histology of bone tumours, and as the incidence of these lesions is so low, and their morphology so diverse, the descriptions given in this book could be more confusing than helpful to the unwary.

AJ FREEMONT

The Kidney in Collagen—Vascular Diseases. Ed E Grishman, J Churg, MA Needle, VS Venkateshan. (Pp 268; \$129.00). Raven Press. 1993. ISBN 0-7817-0021-3.

This monograph draws together concisely a considerable body of information about the kidney in systemic connective tissue disorders. Although it is a multiauthor text the balance and style of presentation are maintained very well throughout. Most chapters deal with individual disease entities and cover, in a systematic manner, the general clinical features, the pathology, and the therapeutic approaches. The illustrations are generally very good, although a few figures appear marginally out of focus. I doubt if this would trouble most readers.

The longest chapter (chapter 4) predictably deals with systemic lupus erythematosus and, like the rest, is of excellent standard. The following chapter on lupus-like syndromes I found particularly informative. Chapter 3 deals with general immunological concepts and pathogenesis of the collagen diseases. It demonstrates clearly that, although much is already known, there is still a great deal that is not understood.

The recurring theme which emerges from the book reminds us that the connective tissue disorders are associated with defects in both cellular and humoral immunity and, in addition, that there may be both genetic and trigger factors involved. Individually they appear very different conditions, yet overlap syndromes are not infrequent and indicate that there must be a similarity of pathogenesis. The temptation is to believe that the mixed histocompatibility complex antigens (either indigenous or evoked) may be important in determining which particular syndrome evolves in a susceptible patient.

I recommend this book unreservedly to those interested in the renal aspects of collagen-vascular diseases.

DR TURNER

Molecular Medicine. An Introductory Text for Students. RJ Trent. (Pp 239; 90 illustrations; paperback £14.95.) Churchill Livingstone. 1993. ISBN 0-443-04635-2.

This competitively priced paperback provides a valuable contribution to an area of undergraduate medicine which is presently inadequately taught despite rapid developments in postgraduate medicine. The book covers a broad area of the applications of the molecular cell sciences to clinical medicine and therefore would also be of interest to some clinicians. The content is up to date and is discussed in an appropriate context so that most sections of the book are easy to read. There are many illustrations, including diagrams and gel photographs which enable the reader to grasp the essential concepts of molecular analysis.

The author tackles some of the controversial areas of the molecular sciences, such as the associated moral issues, with considerable skill. As a guide to the theory and applications of modern molecular techniques in medicine, this book is a superb introductory monograph. Perhaps the major drawback is that the actual practicalities of any of the basic experimental procedures are deliberately not discussed in detail. For example, the skill required for the polymerase chain reaction and subsequent agarose gel analysis is minimal and these aspects would also be of interest to many undergraduates.

None the less this book fulfils its basic objective, namely "to bridge between basic science and the medical specialties". In conclusion, it would be a valuable addition to medical school libraries and perhaps those involved in molecular medicine should be recommended to obtain their own copy.

J JANKOWSKI

Neonatology and Clinical Biochemistry. Green, Morgan. (Pp 213; no price given.) Association of Clinical Biochemists. 1993. ISBN 0-902429-04-3.

This publication is well written and easy to read. It covers the interface between ward and laboratory. Each area is concisely reviewed, both clinically and biochemically, and the subject matter is up to date.

The book will be of value both to neonatologists and clinical chemists, although more so for clinical biochemists and other laboratory workers. The neonatologists are spoilt for choice as they already have competing and established books of similar size, including Robertson's *Manual of Neonatal Intensive Care* and the *Neonatal Vade-Mecum* from Bristol.

This area is one of rapid advance, and the authors are recommended to start working on their second edition now.

R DINWIDDIE
M HJELM

Diagnostic Histopathology of Neuroendocrine Tumours. Ed J M Polak. (Pp 290; 420 illustrations; £95.) Churchill Livingstone. 1993. ISBN 0-443-04480-5.

There is more to this book than the title suggests: as well as providing excellent morphological descriptions of neuroendocrine tumours in different sites, it is an opportunity to view this fascinating group of

neoplasms as a whole, rather than scattered through the various sections of larger texts. The first few chapters hold the key to this and show how far things have progressed since the APUD concept held sway. The opening chapter discusses modern morphological and other investigative methods and is a model of clarity and brevity. There is also a useful summary of oncogenes and neuroendocrine tumours; however, the chapters on "Peptide physiology of human cancer cells and its relationship with autocrine/paracrine growth" and "Transgenic models of neuroendocrine tumours" were a bit heavy on experimental details and somewhat indigestible.

The remaining chapters cover neuroendocrine tumours in most situations. They are all written by experts and provide a wealth of information for the surgical pathologist. The approach varies slightly, but for a book with 26 different authors Professor Polak has managed to maintain consistently high quality throughout. It is difficult to single out any particular section, but I have already had reason to be grateful for Dr Ljungberg's chapter on "Thyroid and parathyroid tumours". This is full of useful practical details and excellent colour illustrations. He even includes his own recipe for oil-red O (for staining parathyroids).

In the lung, where heterogeneity is the rule, the overlap between malignant neuroendocrine tumours and carcinomas is well recognised, and here it is well described by Dr Sheppard. In other organs, such as the gastrointestinal tract, it is less frequently seen and less well documented. Most of us have probably seen a few examples of combined tumours and yet this is an area that receives very little attention in this book. Small cell carcinoma and combined tumours in the urinary tract are not mentioned, and the thymus, which occasionally produces fascinating malignant carcinoid tumours, is also excluded. This is a minor criticism of an otherwise excellent book but I am slightly disappointed that this difficult histogenetic territory remains unexplored.

It has to be said that most of us do not encounter neuroendocrine tumours on a daily basis and the limited funds that we have for buying books have to be used cautiously. At £95 this one is not cheap and would probably not receive high priority in most departments. However, it has no real competitors, and if you are able to permit yourself the occasional indulgence I recommend that you add it to your list.

BJ ADDIS

Recent Advances in Blood Coagulation—6. Ed L. Poller. (Pp 228; 60 illustrations; hardback £39.95.) Churchill Livingstone. 1993. ISBN 0-443-04755-3.

The high standards set by the preceding five volumes have been surpassed by *Recent Advances*—6. This series aims to present a regular and comprehensive overview of this wide ranging field, and has sustained this by combining judicious selection of topics and reviewers with a remarkably short incubation period. This latter attribute lends a freshness to the contributions which is unusual in this genre.

Brommer *et al* present a contemporary practical view of fibrinolysis which culminates in an amusing entreaty against despair, presumably for those left perplexed in spite of this article. Reviews on platelets and molecular markers of in vivo coagulation succinctly describe the notable advances in understanding of biochemical processes in these areas. Bowen and Bloom's article on factor VIII is both instructive and provocative, drawing attention as it does to the need for a clearer understanding of the structure-function implications of mutations in this and other disorders. Reviews on lupus anticoagulants, tissue factor pathway inhibitor, antiplatelet agents, and non-heparin antithrombotics each represent measured views by acknowledged experts, and an article covering the clinically challenging area of thrombosis in infancy is a welcome addition to the sparse literature. It is to be hoped that Poller and Thomson's plea for universal implementation of INR will at last be heard, although this publication may not be the ideal vehicle to "reach those parts ...". The concluding section on key papers from 1991/1992 adds little to the reviews and is the weakest element of an otherwise excellent publication.

In short, this book is thoroughly recommended for all with an interest in blood coagulation, generalists and specialists alike.

SB DAVIES

Neoplasms of the Larynx. Ed A Ferlito. (Pp 634; 346 illustrations; £120.) Churchill Livingstone. 1993. ISBN 0-443-04571-2.

This is a reference book of immense value. The main author has previously edited a three volume book entitled *Cancer of the Larynx* and has this time assembled an international team of authorities, mostly from the USA but with 10 authors from the UK. This is not only a book for pathologists—chapters also cover epidemiology and many aspects of clinical management—it is almost like a pathology book and a clinical book bound together within one cover. The essence of the former is contained in 14 of the 36 chapters, which cover the tumour types including such useful aspects as atypical forms of squamous cell carcinoma, rarer tumours, the use of immunohistochemical markers, and a review of the current TNM classifications. For pathologists, the clinical chapters act as an invaluable source of reference as to what are the main treatment consequences of the various tumour diagnostic labels. The pictures are of exceptional quality and include excellent photomicrographs, photos of macroscopic specimens, large numbers of endoscopic pictures, diagnostic imaging pictures, and many excellent diagrams. This reviewer's favourite clinical picture shows a Japanese patient with a flexible fibre optic endoscope up his nostril, which reminds one of a well-known Japanese television game of endurance and humiliation. The only serious omission for pathologists is the lack of a good description of how to cut up and sample a laryngectomy specimen. However, this is a minor criticism. This is an excellent book which needs to be available to any histopathologist who serves an active ENT clinical team.
