Abstract

The $\alpha 7$ -nicotinic acetylcholine receptor ($\alpha 7$ -nAChR) is a ligand-gated ion channel that is expressed widely in vertebrates and is the principal high-affinity α -bungarotoxin (α -bgtx) binding protein in the mammalian CNS. $\alpha 7$ -nAChRs associate with proteins that can modulate its properties. The $\alpha 7$ -nAChR interactome is the summation of proteins interacting or associating with $\alpha 7$ -nAChRs in a protein complex. To identify an $\alpha 7$ -nAChR interactome in neural tissue, we isolated α -bgtx-affinity protein complexes from wild-type and $\alpha 7$ -nAChR knockout ($\alpha 7$ KO) mouse whole brain tissue homogenates using α -bgtx-affinity beads. Affinity precipitated proteins were trypsinized and analyzed with an Orbitrap Fusion mass spectrometer. Proteins isolated with the $\alpha 7$ -nAChR specific ligand, α -bgtx, were determined to be $\alpha 7$ -nAChR associated proteins. The $\alpha 7$ -nAChR subunit and 120 additional proteins were identified. Additionally, 369 proteins were identified as binding to α -bgtx in the absence of $\alpha 7$ -nAChR expression, thereby identifying nonspecific proteins for $\alpha 7$ -nAChR investigations using α -bgtx enrichment. These results expand on our previous investigations of $\alpha 7$ -nAChR interacting proteins using α -bgtx-affinity bead isolation by controlling for differences between $\alpha 7$ -nAChR and α -bgtx-specific proteins, developing an improved protein isolation methodology, and incorporating the latest technology in mass spectrometry. The $\alpha 7$ -nAChR interactome identified in this study includes proteins associated with the expression, localization, function, or modulation of $\alpha 7$ -nAChRs, and it

INTRODUCTION

The ligand-gated ion channel (LGIC) superfamily comprises a diverse array of structurally similar ionotropic receptors, including nicotinic acetylcholine, γ -aminobutyric acid (GABA)_A, GABA_C, glycine, and 5-HT₃ serotonin receptors.^{1,2} Nicotinic acetylcholine receptors (nAChRs) are pentameric cation channels expressed widely in the mammalian brain and neuromuscular junction.³ Neuronal-type nAChRs are also found in several non-neuronal cell types, including leukocytes.⁴ Eleven neuronal nAChR subunits have been identified in mammals ($\alpha 2$ –7, $\alpha 9$ –10, $\beta 2$ –4).⁵ Receptors containing $\alpha 4\beta 2$, $\alpha 3\beta 4$, and $\alpha 7$ subunits are the most prevalent in the mammalian CNS, with $\alpha 7$ -nAChRs being the most widely expressed homomeric nAChR.³ The $\alpha 7$ -nAChR, composed of five $\alpha 7$ subunits, has several unique physiological traits distinguishing it from other receptor subtypes. For example, the $\alpha 7$ -nAChR has a higher Ca²⁺:Na⁺ permeability ratio than other nAChR subtypes, suggesting a greater physiological role in Ca²⁺ signaling pathways.^{1,6}

The investigation of $\alpha 7$ -nAChRs has been facilitated by the availability of several high-affinity, selective ligands, including α -bungarotoxin (α -bgtx) and methyllycaconitine (MLA). Radiolabeled α -bgtx and MLA binding in murine brain tissue has been used extensively to establish $\alpha 7$ -nAChR levels and distribution.^{7,8} Studies using ¹²⁵I- α -bgtx have investigated changes in $\alpha 7$ -nAChR expression during development, as well as drug-induced changes in $\alpha 7$ -nAChR expression in whole brain and specific brain regions.^{9,10} Interstrain variability of $\alpha 7$ -nAChR levels and distribution has also been investigated using radiolabeled α -bgtx.¹¹ α -Bgtx is well-characterized as having high-affinity (nM K_d) for $\alpha 7$ -nAChRs, and as such is a reliable, commercially available ligand for affinity purification of $\alpha 7$ -nAChRs.

Proteins associating with a target of interest, in our case $\alpha 7$ -nAChR, are collectively known as an interactome. Receptor interactomes may include both direct interactions with the

receptor and indirect interactions with the receptor-protein complex. Certain receptor-protein interactions regulate receptor biogenesis and function. These protein interactions may impact $\alpha 7$ -nAChR assembly,¹² affect trafficking and targeting,^{13,14} contribute to signaling,¹⁵ and/or be medically relevant.^{16,17} Mass spectrometry-based protein identification is a well-established and valuable tool for determining protein interactomes.^{18,19}

The murine brain is an ideal model for the investigation of $\alpha 7$ -nAChR interacting proteins, as various strains and genotypes are readily available for study, and technologies to establish new transgenic and mutant mouse models have been developed. The described work expands on prior proteomic studies using α -bgtx as a tool for affinity purification of $\alpha 7$ -nAChRs. Here, we incorporate several new methods enabling the reliable detection of murine $\alpha 7$ -nAChRs and associated proteins, and we explore both $\alpha 7$ -nAChR and α -bgtx-specific protein controls.²⁰

Several proteomic comparisons are described in our investigation. The first comparison is an analysis of α -bgtx-affinity purified proteins from wild-type and $\alpha 7$ KO mice. This comparison allows identification of $\alpha 7$ -nAChR specific interacting proteins. The second comparison is an analysis of proteins that bind to α -bgtx in the absence of $\alpha 7$ -nAChRs, using $\alpha 7$ KO mice to identify those proteins that do not interact with $\alpha 7$ -nAChRs, but that do interact with α -bgtx-affinity beads. The GABA_A receptor (GABA_AR) has recently been shown to have affinity for α -bgtx in mouse tissue.²¹ Given this, the use of $\alpha 7$ -nAChR-specific controls, rather than α -bgtx-specific controls, is of paramount importance for proteomic investigations when using α -bgtx-affinity purification to exclude non- $\alpha 7$ -nAChR, α -bgtx interacting proteins. Some of the previously reported $\alpha 7$ -nAChR associated proteins may, in fact, associate with another α -bgtx-affinity protein and not with the $\alpha 7$ -nAChR.

In summary, the work described here defines a murine whole brain $\alpha 7$ -nAChR interactome, while also identifying the receptor subunit itself. Additionally, the availability of $\alpha 7$ KO mice and α -bgtx immobilization techniques allows for the identification of α -bgtx-affinity proteins that should not be included in the $\alpha 7$ -nAChR interactome.

EXPERIMENTAL SECTION

Mouse Brain Tissue

Whole brains of adult, male, wild-type C57Bl/6 or FVB mice, as well as adult, male, $\alpha 7$ KO FVB mice, were isolated and frozen at -80°C before use. All protocols were approved by the Institutional Animal Care and Use Committee of Brown University (protocol 1201004).

Preparation of α -bgtx-Sepharose Affinity Beads

Cyanogen bromide-activated Sepharose beads 4B (Sigma-Aldrich, St. Louis, MO) (1g) were hydrated in 5 mL of cold 1 mM HCl for 30 min and washed with 500 mL of 1 mM HCl over a coarse glass filter. The beads were added to 7.5 mL coupling buffer (0.25 M NaHCO₃, 0.5 M NaCl, pH 8.3) and subsequently centrifuged at 4°C for 5 min at 1500g. The supernatant was discarded, and the pellets were resuspended in 7.5 mL coupling buffer containing 4 mg of α -bgtx (0.53 mg α -bgtx/mL coupling buffer/g Sepharose 4B beads). Bead/ligand mixtures were incubated with gentle agitation at 4°C for 18 h. The beads were subsequently pelleted

and resuspended in 7.5 mL of 0.2 M glycine in 80% coupling buffer and 20% ultrapure water, and they were gently agitated overnight at 4 °C to block unreacted groups on the beads. The beads were then washed over a coarse glass filter, first with 100 mL of 0.1 M NaHCO₃, 0.5 M NaCl, pH 8.0, then 100 mL of 0.1 M NaCH₃CO₂, 0.5 M NaCl, pH 4.0, again with 100 mL of 0.1 M NaHCO₃, 0.5 M NaCl, pH 8.0, 100 mL coupling buffer, and last twice with 100 mL Tris-buffered saline (TBS: 150 mM NaCl, 50 mM Tris, pH 7.5). Washed beads were resuspended in TBS for storage at 4 °C. Prior to use, stock α -bgtx-affinity beads were uniformly resuspended into a slurry, and aliquots were centrifuged at 4 °C for 5 min at 1500g. Pelleted beads were resuspended to make a 50/50 slurry with homogenization buffer (50 mM NaCl, 50 mM NaH₂PO₄, 2 mM EDTA, 2 mM EGTA, pH 7.4) before use.

Mouse Whole Brain Membrane Protein Solubilization

Mouse whole brains were dissociated in homogenization buffer (50 mM NaCl, 50 mM NaH₂PO₄, 2 mM EDTA, 2 mM EGTA, pH 7.4) with 30 strokes of a Potter-Elvehjem glass homogenizer on ice. Membrane fragments were isolated following centrifugation at 97 000g for 60 min at 4 °C. Membrane pellets were then treated with solubilization buffer (50 mM NaCl, 50 mM NaH₂PO₄, 2 mM EDTA, 2 mM EGTA, 2% Triton X-100, pH 7.4) with 40 strokes of a Potter-Elvehjem glass homogenizer on ice and incubated for 3 h at 4 °C with agitation to solubilize membrane-bound proteins. Following a second centrifugation at 100 000g for 60 min at 4 °C, the solubilized membrane fraction was recovered in the supernatant. All buffers used to isolate the solubilized membrane fraction were supplemented with protease inhibitors (Roche, Basel, Switzerland). Protein content of solubilized membrane fractions was determined using a bicinchoninic acid (BCA) assay (Pierce, Waltham, MA).

α 7-nAChR and Associated Protein Complex Isolation

Immediately following the isolation of solubilized membrane fractions, a volume containing 25 mg of solubilized protein was incubated with 200 μ L of the 50/50 α -bgtx-affinity bead/homogenization buffer slurry for 18 h at 4 °C with gentle agitation. α -Bgtx-affinity beads were washed with homogenization buffer before use. Control samples were either solubilized receptor preparations from α 7 KO mice (i.e., α 7-nAChR-specific control) or control beads lacking conjugated α -bgtx (i.e., α -bgtx-specific control) (Figure 1). Following the incubation, α -bgtx-affinity beads and bound protein were transferred to Pierce Spin Cups (Thermo Fisher Scientific Inc., Waltham, MA) and washed three times with solubilization buffer. After the beads and bound protein were washed, the total affinity-immobilized α 7-nAChR content was either measured using a ¹²⁵I- α -bgtx radioligand binding assay, or the isolated proteins were eluted for mass spectrometry analysis (Figure 2).

Radioligand Binding Assays

An on-bead ¹²⁵I- α -bgtx binding assay was used to confirm α 7-nAChR presence on α -bgtx-affinity beads and the absence of α 7-nAChRs on control beads. α -Bgtx is able to affinity immobilize and concurrently detect α 7-nAChRs, as these receptors contain multiple α -bgtx binding sites.²² Affinity-immobilized α 7-nAChR content was determined by incubating samples with 5 nM ¹²⁵I- α -bgtx (PerkinElmer, Boston, MA) for 1 h at room temperature.

Nonspecific binding was determined in controls by the inclusion of 1 μ M unlabeled α -bgtx prior to addition of 125 I- α -bgtx. Following incubation with 125 I- α -bgtx, beads were washed three times with solubilization buffer and gamma emissions were measured using a Wallac 1275 minigamma gamma counter.

Mass Spectrometry Sample Preparation, Precipitation, and In-Solution Trypsin Digestion

Affinity beads were washed three times with solubilization buffer followed by a single, high-salt solubilization buffer wash (2.05 M NaCl, 50 mM NaH₂PO₄, 2 mM EDTA, 2 mM EGTA, 2% Triton X-100, pH 7.4) to enhance the identification of α 7-nAChR by eluting non- α 7-nAChR protein from the affinity beads. Immobilized α 7-nAChR protein complexes were specifically eluted from the α -bgtx-affinity beads by incubation with 100 μ L 1 M carbachol (Sigma-Aldrich, St. Louis, MO) in 20 mM HEPES, pH 8.0 for 30 min with agitation every 5 min at room temperature. α -Bgtx-affinity beads were allowed to sediment, and the eluted proteins in the supernatant were removed and stored at -80°C until preparation for mass spectrometry analysis. The quantity of eluted protein was determined using the Pierce BCA Protein Assay Kit. To prepare for mass spectrometric analysis, samples were thawed and disulfide residues were reduced with 47 mM TCEP in 20 mM HEPES, pH 8.0 for 1 h at 60°C . Samples were alkylated with 83 mM iodoacetamide in 20 mM HEPES, pH 8.0 for 1 h in the dark at room temperature, and then concentrated and purified via precipitation using a BioRad ReadyPrep 2-D Cleanup Kit (BioRad, Hercules, CA). Precipitated protein was resuspended in 50 mM ammonium bicarbonate, pH 7.8 supplemented with 100 ng trypsin (Promega, Madison, WI) and digested overnight in-solution at 37°C . Both high-salt solubilization buffer washes and 1 M carbachol elutions were analyzed using mass spectrometry.

HPLC and Mass Spectrometry Analysis

Each sample was desalted using a StageTip and dried via vacuum centrifugation. Peptides were reconstituted in 5% acetonitrile (ACN), 5% formic acid for LC-MS/MS analysis using an Orbitrap Fusion mass spectrometer (Thermo Fisher Scientific, San Jose, CA) coupled to an in-line Proxeon EASY-nLC 1000 liquid chromatography (LC) pump (Thermo Fisher Scientific, San Jose, CA). Peptides (approximately 2 μ g) were fractionated on a microcapillary column (75 μ m inner diameter) packed with $\sim$ 0.5 cm of Magic C4 resin (5 μ m, 100 $\text{\AA}$, Michrom Bioresources) followed by $\sim$ 35 cm of GP-18 resin (1.8 μ m, 200 $\text{\AA}$, Sepax, Newark, DE). Separation of peptides was achieved during a 3 h gradient of 6 to 26% ACN in 0.125% formic acid at a rate of 350 nL/min. The scan sequence began with an MS1 spectrum (Orbitrap analysis; resolution 120 000; mass range 400–1400 m/z; automatic gain control (AGC) target 2×10^5 ; maximum injection time 100 ms). Precursor ion selection for MS/MS analysis was performed using a TopSpeed of 2 s or TopN of 20 ions. MS/MS analysis consisted of collision-induced dissociation (CID) (quadrupole ion trap analysis; automatic gain control (AGC) 1×10^4 ; normalized collision energy (NCE) 35; maximum injection time 150 ms). Peak lists of MS/MS spectra were created using msconvert.exe (v. 2.2.3300) available in the ProteoWizard tool.²³ Experimental spectra were bioinformatically matched in silico against theoretical spectra of a concatenated target-decoy (sequence-reversed) *Mus musculus* database (Uniprot, March 2015) using the Mascot algorithm (Matrix Science, Boston, MA). Database searches used the following parameters: up to two

missed trypsin cleaves allowed, 7 ppm MS tolerance, 20 ppm MS/MS tolerance, fixed carbamidomethyl modification, and variable methionine oxidation modification.

Data Analysis

Mascot search results were loaded into ProteoIQ (Premier Biosoft, Palo Alto, CA) for further analysis. All identified proteins were initially filtered using a 1% protein false-discovery rate (FDR) calculated with the PROVALT algorithm and a minimum peptide length of six amino acids. Inclusion criteria for $\alpha 7$ -nAChR and α -bgtx interacting proteins were as follows: 90% group probability score of correct identity assignment using the ProteinProphet algorithm, presence in two or more independent replicates, and 0% probability score in controls.^{24–26} Both the PROVALT and ProteinProphet algorithm are integrated into ProteoIQ. Only Top and Co-Top identifications (i.e., identifications that include all peptide data in a protein group) were used during analysis. For mass spectrometry analysis, each condition was analyzed with five biological replicates. Identified $\alpha 7$ -nAChR-specific interacting proteins were categorized by their reported Gene Ontology (GO) biological process and cellular compartment terms using Search Tool for Recurring Instances of Neighboring Genes (STRING) (version 10.5), and Database for Annotation, Visualization and Integrated Discovery (DAVID) (version 6.8).^{27,28} If neither classification system had an entry for an identified protein, the protein was classified as unattributed. STRING was used to visualize interactomes, analyze possible GO Term enrichments for cellular compartment, molecular function or biological process, as well as illustrate known connections between identified interacting proteins.²⁸ FDRs for enriched ontologies were reported using STRING analysis. DAVID was used to identify ontologies represented in the identified proteomes that may not be enriched. Results from DAVID were reported as *p*-values using the Benjamini–Hochberg procedure for correcting multiple comparisons.

RESULTS AND DISCUSSION

Immobilization of $\alpha 7$ -nAChRs and Associated Proteins Using α -bgtx-Affinity Beads

Solubilized C57Bl/6 and FVB murine brain tissue preparations from both wild-type and $\alpha 7$ KO FVB controls were incubated with α -bgtx-affinity beads or control beads lacking conjugated α -bgtx. Using the optimized α -bgtx-affinity immobilization conditions, 5.4 ± 0.5 fmol ^{125}I - α -bgtx binding per mg solubilized protein was measured in samples from C57Bl/6 mouse tissue and no observable binding was detected using control beads (Figure 3A). In wild-type preparations of FVB mouse brain tissue, 6.4 ± 1 fmol ^{125}I - α -bgtx binding per mg solubilized protein was measured, and no detectable binding was observed using $\alpha 7$ KO preparations or when incubating wild-type tissue with control beads (Figure 3B).

A primary aim for this work was to establish methods for identifying $\alpha 7$ -nAChR peptides, as well as providing an updated and well-controlled $\alpha 7$ -nAChR interactome from mouse brain tissue using α -bgtx-affinity immobilization and mass spectrometry. To achieve this aim, several methodological changes were made to our previous study design.²⁰ In addition to the changes in homogenization/solubilization and bead conditions, a stringent “high-salt wash” (2 M NaCl, 50 mM NaH_2PO_4 , 2 mM EDTA, 2 mM EGTA, 2% Triton X-100, pH 7.4) was included prior to elution with carbachol to reduce nonspecific binding to beads. High-

salt washes did not reduce α -bgtx binding to immobilized $\alpha 7$ -nAChRs in the SH-SY5Y neuroblastoma-derived cell line that endogenously expresses $\alpha 7$ -nAChRs (Supplemental Figure S-1).²⁹ However, as 2 M NaCl could displace some protein interactions, the high-salt washes were also analyzed by mass spectrometry. For both the $\alpha 7$ -nAChR and non- $\alpha 7$ -nAChR, α -bgtx interactomes, the distinction was made between proteins that were eluted in the high-salt wash and proteins that were eluted by carbachol. A second α -bgtx interactome, only including proteins eluted with carbachol in wild-type tissue, was also investigated.

Identification of $\alpha 7$ -nAChR Subunit Peptides and $\alpha 7$ -nAChR Interacting Proteins

Comparing α -bgtx purified proteins from wild-type tissue with proteins purified from $\alpha 7$ KO tissue allowed identification of an $\alpha 7$ -nAChR-specific interactome. Proteins from both experimental and negative control samples were removed sequentially by a high-salt wash, followed by carbachol elution. Fifty-two $\alpha 7$ -nAChR interacting proteins were eluted with carbachol, including a peptide of the $\alpha 7$ -nAChR subunit, FPDGQIWKPDILLYNSADER (Table 1, Supplemental Tables S-1). Seventy $\alpha 7$ -nAChR interacting proteins were identified in high-salt washes. An interactome of 121 $\alpha 7$ -nAChR interacting proteins was identified by combining identifications from both high-salt washes and carbachol elutions (Figure 4A). Peptides from $\alpha 7$ subunits were not identified in high-salt washes (Supplemental Tables S-1). A single protein, plakophilin-1, was identified in both the high-salt washes and carbachol-eluted fractions. Proteins identified as $\alpha 7$ -nAChR interacting proteins in high-salt washes (i.e., not identified in $\alpha 7$ KO control samples) were not included in the $\alpha 7$ interactome if the protein was subsequently identified in both experimental and $\alpha 7$ KO controls after carbachol elution.

Several studies have previously investigated $\alpha 7$ -nAChR interactomes using mass spectrometry.^{20,30,31} Paulo et al. first utilized α -bgtx-affinity beads to isolate protein complexes from wild-type and $\alpha 7$ KO mice to investigate the $\alpha 7$ -nAChR interactome.²⁰ While the methodology used in the Paulo et al. study is similar to that used here, no peptides originating from the $\alpha 7$ -nAChR subunit were identified by mass spectrometric analysis. A second study used α -bgtx-affinity to isolate $\alpha 7$ -nAChRs and to identify the receptor as well as their protein of interest, PMCA2, using rat brain extracts and mass spectrometry.³¹ However, this study did not report sufficient details on the identification of $\alpha 7$ -nAChR peptides and did not utilize an $\alpha 7$ -nAChR-specific control for the analysis. More recently, $\alpha 7$ -nAChR subunit peptides have been identified, along with interacting proteins, in the rat pheochromocytoma-derived cell line PC12 using anti- $\alpha 7$ -nAChR antibody conjugated affinity beads and mass spectrometry.³⁰ Several commercially available antibodies for nAChRs have been reported to have inconsistent characteristics, and their use for immunoprecipitation can be problematic.^{32,33} α -Bgtx provides a reliable, commercially available ligand for affinity purification of $\alpha 7$ -nAChRs.

The sequenced $\alpha 7$ -nAChR subunit peptide, FPDGQ-IWKPDILLYNSADER, was identified in wild-type samples of both FVB and C57Bl/6 mice and was not identified in either $\alpha 7$ -nAChR-specific and α -bgtx-specific controls (Table 1, Supplemental Tables S-1, S-8). The same peptide was identified previously in SH-SY5Y samples (not shown) and in transfected SH-EP1 cells, two human neuroblastoma-derived cell models of $\alpha 7$ -nAChR expression.³⁴ In

addition to identifying $\alpha 7$ -nAChRs, GABA_AR subunits, recently shown to bind α -bgtx, were identified in both α -bgtx and non- $\alpha 7$ -nAChR, α -bgtx interactomes, but not in the $\alpha 7$ -nAChR interactome (Table 1).^{21,35} This observation stresses the importance of controls that are $\alpha 7$ -nAChR-specific when using α -bgtx-affinity immobilization.

The proteins of the $\alpha 7$ -nAChR interactome were characterized by their known or predicted cellular compartments (Supplemental Tables S-2, S-3), molecular functions (Supplemental Tables S-4, S-5), and biological processes, using both STRING and DAVID. Interactome associated Kyoto Encyclopedia of Genes and Genomes (KEGG) pathways were identified using DAVID. STRING is useful for highlighting enriched protein characteristics in a proteome, whereas DAVID is useful for highlighting proteins of a particular characteristic, whether enriched or not. No enriched biological processes were identified by STRING or DAVID; though general biological process ontologies were identified by DAVID (Supplemental Tables S-6). STRING was used to visualize a protein–protein interaction map of the $\alpha 7$ -nAChR interactome (Figure 7).

The proteins of the $\alpha 7$ -nAChR interactome identified in this study are enriched for cellular compartments involved with receptor biogenesis (Golgi-associated vesicle, GO:0005798, FDR 0.01), trafficking (cytoplasmic vesicle membrane, GO:0030659, FDR 0.009), the receptor's site of physiological activity (plasma membrane, GO:0005886, FDR 0.008), and receptor turnover (endosome, GO:0005768, FDR 0.012). Interestingly, localization to the mitochondria (GO:0005739, FDR 0.0004) was also enriched, agreeing with previous studies that identified $\alpha 7$ -nAChR function in the mitochondrial membrane.³⁶ Proteins localized in neuron projections (GO:0043005, FDR 0.008), including $\alpha 7$ subunits, were also enriched, which is consistent with the observation that development of neuron projections (i.e., neurites) is mediated by $\alpha 7$ -nAChRs (Figure 5, Figure 7).³⁷

The identification of interacting proteins is an important step toward understanding where receptors were localized, their associated molecular functions, and how those functions contribute to biological processes. This understanding may help elucidate how alterations of the receptors' interactors can lead to or contribute to human disease, as well as help identify possible therapeutic targets. STRING and KEGG pathway analysis of the identified $\alpha 7$ -nAChR interactome showed enrichment for several molecular functions of potential relevance to human disease (Figure 6, Table 2). STRING and KEGG analysis was supplemented by a literature review to explore which $\alpha 7$ -nAChR interacting proteins that were associated with human diseases, such as Alzheimer's disease, insulin resistance, and Parkinson's disease in the literature. Thirty-one selected human disease-related proteins were identified in the $\alpha 7$ -nAChR interactome and are presented in Table 3.

Several of these identified proteins are related to Alzheimer's disease, which is a progressive form of dementia pathologically characterized by extracellular plaques containing β -amyloid (A β) and intracellular neurofibrillary tangles containing hyperphosphorylated tau proteins.^{38,39} Alzheimer's disease is also characterized by loss of cholinergic neurons, resulting in a reduction of nAChR protein expression. Numerous studies have investigated the connection between $\alpha 7$ -nAChRs and Alzheimer's disease.^{40,41} Activation of $\alpha 7$ -nAChRs reduces neuroinflammation and is considered neuroprotective against Alzheimer's disease related

toxicities (e.g., $A\beta_{1-42}$ toxicity).⁴²⁻⁴⁴ These observations have led to the pursuit of cholinergic therapeutics for the treatment of Alzheimer's disease.^{45,46} Proteins associated with both $A\beta$ and hyper-phosphorylation of tau proteins, the two major components of Alzheimer's disease pathology, were identified in the $\alpha 7$ -nAChR interactome (Table 2, Table 3).

One of the molecular function enrichments identified during STRING analysis was tau-protein kinase activity (GO: 005021, FDR 0.02) (Figure 6, Figure 7). The phosphorylation of tau by multiple proteins is a hallmark of Alzheimer's disease pathology and therefore of interest for the study of Alzheimer's disease. The three interactors identified were 5'-AMP-activated protein kinase catalytic subunit alpha-1 (Prkaa1), MAP/ microtubule affinity-regulating kinase 2 (MARK2), and MAP/microtubule affinity-regulating kinase 4 (MARK4). Prkaa1 is one of the subunits of 5'-AMP-activated protein kinase (AMPK). AMPK has been shown to phosphorylate tau proteins in response to $A\beta$.⁴⁷ Two AMPK-related proteins, MARK2 and MARK4, were also identified.⁴⁸ As with AMPK, both MARK2 and MARK4 have been shown to phosphorylate tau proteins.⁴⁹ It has also been shown by several groups that MARK2 is phosphorylated by glycogen synthase kinase 3 β (GSK3 β), a principle tau kinase, inactivating MARK2.⁵⁰ We reviewed the literature to identify additional AD related proteins that may not be represented in STRING (Table 3). Identified proteins, such as insulin-degrading enzyme, that are associated with Alzheimer's disease but not highlighted by STRING analysis may affect the following: (1) interaction with APP or $A\beta$;⁵¹⁻⁵⁴ (2) altered expression or function in Alzheimer's disease;⁵⁵ (3) or have a genetic association.⁵⁶

The $\alpha 7$ -nAChR interactome reported in this study also includes proteins associated with insulin sensitivity or resistance,⁵⁷⁻⁶² with changes in gene or protein expression,⁶³ with genetic links to diabetes,⁶⁴ with alteration of biological processes central to diabetes,^{65,66} or with the effects of smoking behavior on diabetes (Table 3).⁶⁷ STRING analysis of $\alpha 7$ -nAChR interacting proteins identified carbohydrate derivative binding as an enriched molecular function (GO: 0097367, FDR 0.02) (Figure 6, Figure 7). The identification of proteins associated with both insulin resistance and Alzheimer's disease is particularly interesting as shared similarities exist in some of the abnormal carbohydrate derivative sensitivity (e.g., to D-glucose) and metabolic pathways involved in both of these medically relevant conditions.⁶⁸⁻⁷¹ For example, individuals with type 2 diabetes mellitus (i.e., insulin resistance) are more susceptible to an increased risk for developing Alzheimer's disease.
72-74

As with Alzheimer's disease, neuroprotection mediated by $\alpha 7$ -nAChR activation has been demonstrated in several models of Parkinson's disease (PD).⁷⁵ Stimulation of $\alpha 7$ -nAChRs can also ameliorate dyskinesia in models of Parkinson's disease.^{76,77} Several proteins in the $\alpha 7$ -nAChR interactome reported in this study are genetically associated with certain populations of patients with Parkinson's disease (Table 3).^{78,79} Additionally certain proteins in the $\alpha 7$ -nAChR interactome have altered expression levels in PD patients, such as ATP5J, a component of a mitochondrial ATP synthase (Table 2, Table 3).⁸⁰ Additional proteins identified in this study are associated with neuroprotection against α -synuclein toxicity in Parkinson's disease or are activated by α -synuclein.^{81,82} Overall, $\alpha 7$ -nAChR function may be involved in the molecular dysfunction of multiple diseases and the $\alpha 7$ -nAChR

interactome may therefore be of interest as a potential therapeutic target for the treatment of those diseases. Identification of the protein–protein interactions of $\alpha 7$ -nAChRs may help us understand how the receptor–protein interactions with these ion channels may be involved with human disease and may lead to the development of novel therapeutics.

A connection between $\alpha 7$ -nAChRs and Alzheimer's disease from human post-mortem studies is undeniable, but the details of the association still need to be clarified. The findings presented in this study may be used as a foundation for the study $\alpha 7$ -nAChRs using animal models of human disease, such as Alzheimer's disease (AD) rodent models.

An investigation of $\alpha 7$ KO mice crossed with an amyloid precursor protein (APP) overexpressing mouse line ("APP $\alpha 7$ -KO") demonstrated that APP $\alpha 7$ KO mice demonstrated the same levels of APP and A β as control APP mice, but did not suffer cognitive defects of the same magnitude.⁸³ It has been shown that extracellular A β binds $\alpha 7$ -nAChRs and enhances the internalization of the receptors.^{17,84} This could increase A β intracellularly, leading to increased toxicity and possibly cell death. This hypothesis would support the fact that while $\alpha 7$ KO mice demonstrate the same levels of APP and A β as wild-type mice, deletion of $\alpha 7$ -nAChRs can reduce A β internalization and therefore reduce toxicity resulting in reduced cognitive loss. Thus, prevention of $\alpha 7$ -nAChR internalization caused by A β may be a therapeutic target for the alleviation of cognitive decline in AD, not necessarily through the prevention of A β aggregation, but rather through amelioration of A β toxicity.

Fifty-five murine $\alpha 7$ -nAChR interacting proteins have been previously reported by Paulo et al., 2009, using α -bgtx-affinity protein isolation and mass spectrometry. Comparing the 55 proteins from this previous study to our present findings: a single protein, gelsolin, was identified in both; 6 were not identified in the present study; and the remaining 48 were identified in the $\alpha 7$ KO control samples in the present study and therefore were not included as $\alpha 7$ -nAChR interacting proteins. There were several changes in experimental methods that may account for the differences in the proteins identified in this study compared with the previous study. These methodological changes were made to increase $\alpha 7$ -nAChR isolation efficiency to address a concern expressed by Paulo et al., 2009, that while immunoblots identified the $\alpha 7$ subunit in the carbachol elution from the α -bgtx affinity beads, the subunit was not identified using mass spectrometry, despite the identification of $\alpha 7$ -nAChR interacting proteins.

The general workflow described in the present study is similar to the previous study, with changes in experimental methods to increase the efficiency of $\alpha 7$ -nAChR isolation, including changes in α -bgtx levels conjugated to beads (four times the amount used in the previous study), in homogenization buffer selection, in trypsin digest (in-gel vs in-solution), and in the sensitivity of available mass spectrometry technology. These alterations were made specifically to enable the identification of $\alpha 7$ -nAChR peptides in α -bgtx-affinity enriched samples after analysis using mass spectrometry. Using a protocol similar to Paulo et al., 2009, 1.5 ± 0.4 fmol ^{125}I - α -bgtx/mg protein was observed. After our modifications, and as shown in Figure 3, we were able to isolate >5 fmol ^{125}I - α -bgtx/mg protein. In addition to procedural changes, the Orbitrap Fusion mass spectrometer used in the present study is more sensitive than the LTQ-Orbitrap mass spectrometer used in the previous study. These

methodological changes may have increased our ability to detect proteins as well as the nonspecific interactions with α -bgtx-affinity beads. These qualities, while advantageous for detecting $\alpha 7$ -nAChRs, would also affect proteins in control samples, identifying proteins in both that were not detected using the methods in the previous study. The changes made to our workflow for our present study did result in the identification of $\alpha 7$ -nAChR subunit peptide by mass spectrometry.

α -Bungarotoxin Interacting Proteins

In addition to the murine $\alpha 7$ -nAChR interactome, we also investigated proteins interacting with α -bgtx. To derive meaningful proteomic data from α -bgtx affinity-immobilization, appropriate controls must be utilized to identify nonspecific interactions that should be excluded from the analysis of the $\alpha 7$ -nAChR interactome. In total, 183 proteins were identified in the α -bgtx interactome. Of the total of 183 proteins, 7 (4% of the total α -bgtx interactome) proteins were identified in both the carbachol-eluted α -bgtx and $\alpha 7$ -nAChR interactomes. In contrast, 44 (24% of the total α -bgtx interactome) proteins were identified in both the α -bgtx interactome and the non- $\alpha 7$ -nAChR, α -bgtx interactome (Figure 8). The large number of proteins that are shared between the two α -bgtx interactomes, regardless of $\alpha 7$ -nAChR expression, demonstrates the importance of using appropriate controls. The α -bgtx interactome was identified in C57Bl/6, whereas the $\alpha 7$ -nAChR and non- $\alpha 7$ -nAChR, α -bgtx interactomes were identified in FVB. While strain differences may contribute to reduced levels of overlap between interactomes, the 24% of interacting proteins that are still identified between the α -bgtx and non- $\alpha 7$ -nAChR, α -bgtx interactomes is difficult to ignore. The distinction between α -bgtx-selective and $\alpha 7$ -nAChR-selective controls is also important as other proteins have recently been reported to bind to α -bgtx in mammalian brain tissue, most notably several GABA_AR subtypes.^{21,35}

Proteins isolated on α -bgtx-affinity and control beads from $\alpha 7$ -nAChR KO samples were compared to identify proteins that interacted with α -bgtx in the absence of $\alpha 7$ -nAChR expression. We identified a total of 369 proteins interacting with α -bgtx in the absence of $\alpha 7$ -nAChR (192 high-salt wash-eluted, 232 carbachol-eluted, 55 shared in both elutions) (Figure 4B, Supplemental Tables S-7). These proteins can therefore be considered as possible non- $\alpha 7$ -nAChR specific “contaminants” for studies using α -bgtx-affinity to investigate $\alpha 7$ -nAChR-protein interactions. Our data show that the $\beta 1$ GABA_AR subunit was identified in elutions from α -bgtx beads in $\alpha 7$ KO samples (Table 1D). This finding was consistent with the identification of the $\beta 3$ GABA_AR subunit from α -bgtx-affinity bead versus control bead comparisons in WT mice (Supplemental Tables S-8). Both $\beta 1$ and $\beta 3$ subunits have been associated with GABA_ARs with affinity for α -bgtx.^{21,35} Moreover, GABA_AR peptides were absent in $\alpha 7$ -nAChR interactomes. The comparison of carbachol-eluted proteins from α -bgtx-affinity beads to proteins eluted from control beads identifies proteins by α -bgtx-affinity rather than $\alpha 7$ -nAChR specificity. Interestingly, the non- $\alpha 7$ -nAChR, α -bgtx-interactome had large overlap (13%) between the high-salt wash elutions and carbachol elution fractions compared to the identified $\alpha 7$ -nAChR interactome (1% overlap) or α -bgtx interactome (1%).

Two different mouse strains were used in this study. C57Bl/ 6J (“C57Bl/6”) mice, the same mouse strain used in our previous investigations, were used to identify the α -bgtx interactome.²⁰ FVB/NJ (“FVB”) mice were used in our investigation of the $\alpha 7$ -nAChR interactome and the non- $\alpha 7$ -nAChR, α -bgtx interactome, due to the availability of the $\alpha 7$ KO genotype in this strain. With the advantage of large litter sizes and zygote pronuclei, FVB are often used in transgenic studies.⁸⁵ As is common when comparing any two mouse strains, genetic differences exist between C57 and FVB mice.⁸⁶ These differences could lead to deviations in protein levels and the composition of nAChR interacting proteins, although no cross-strain comparisons were performed. Several reports suggest that in general, $\alpha 7$ KO mice do not present significant changes in physical, neurological, or behavioral phenotype compared to wild-type mice; however, several distinct phenotypes have been reported in $\alpha 7$ KO mice.^{87–89} Depression-like phenotypes mediated through BDNF-TRKB signaling have been shown in $\alpha 7$ KO mice.⁹⁰ Neuronal TRKB (ntrk2) was identified in this study, suggesting that depression-like phenotypes in knockout mice may be caused by the lack of interaction between ntrk2 and the $\alpha 7$ -nAChR.

CONCLUSIONS

Here we compared the α -bgtx-affinity proteins from both $\alpha 7$ -nAChR wild-type and KO mouse whole brain tissue to identify both affinity purified $\alpha 7$ -nAChR as well as novel interacting proteins. This investigation also characterized two additional murine interactomes: a total α -bgtx interactome and a non- $\alpha 7$ -nAChR, α -bgtx interactome. The data presented here expanded upon our previous investigations of $\alpha 7$ -nAChR interacting proteins using α -bgtx-affinity bead isolation, differentiating between $\alpha 7$ -nAChR- and α -bgtx-specific negative controls, and using the latest mass spectrometry technology.

Including the $\alpha 7$ -nAChR subunit, 121 $\alpha 7$ -nAChR interacting proteins were identified in this study. These interacting proteins were identified in two fractions: a high-salt wash eluted- and a carbachol-eluted fraction from the same α -bgtx-affinity immobilized samples. Additionally, the two α -bgtx interactomes identified in this work were novel and highlight proteins that should be viewed cautiously if using α -bgtx for affinity proteomics when an $\alpha 7$ -nAChR-specific control is not available.

Using α -bgtx to affinity-immobilize $\alpha 7$ -nAChRs provides an alternative to immunoprecipitation for isolating $\alpha 7$ -nAChRs and its interacting proteins. Many groups have reported inconsistencies when using certain nicotinic receptor-specific antibodies, such as detecting immunoreactivity in nAChR null models.^{32,33} Based on these observations, using antibodies for nAChR affinity proteomics may lead to inaccurate findings. As such, α -bgtx may be advantageous because of its well-characterized affinity for both human and murine $\alpha 7$ -nAChRs.

Affinity purification of $\alpha 7$ -nAChRs with α -bgtx is not without difficulties. The toxin's high affinity may prove problematic; thus, elution conditions must be more stringent than those needed with antibody methodologies. The issue of selectivity has also been raised with several GABA_AR subtypes shown to have α -bgtx-affinity. This concern was alleviated by using appropriately selected $\alpha 7$ -nAChR-specific control groups. We demonstrated that beads

without conjugated ligand were not sufficient to achieve $\alpha 7$ -nAChR specificity in α -bgtx-affinity proteomics. This point was highlighted by the identification of GABA_AR peptides in both α -bgtx inter-actomes, whereas GABA_AR peptides were not identified in the $\alpha 7$ -nAChR-specific interactome.

The strategies and data described in this work highlight improvements in methodologies for isolating the $\alpha 7$ -nAChR and associated protein complexes from the murine whole brain. The positive identification in this study of the $\alpha 7$ -nAChR subunit, and its associated receptor interactome, established a foundation for the investigation of $\alpha 7$ -nAChR interacting proteins in murine models of human disease. These investigations open new possibilities for investigating proteomic alterations in $\alpha 7$ -nAChR interacting proteins caused by or contributing to specific disease states.

Figure 1.

Murine whole brain experimental design. Solubilized protein was isolated from male (A) wild-type or (B) $\alpha 7$ KO mice and was incubated with Sepharose α -bgtx-affinity beads or Sepharose beads without α -bgtx (i.e., control beads). The $\alpha 7$ -nAChR interactome was identified using FVB $\alpha 7$ KO extracts as $\alpha 7$ -nAChR-specific controls, which were analyzed in parallel with FVB wild-type samples. For non- $\alpha 7$ -nAChR, α -bgtx interactome investigations, proteins were identified from $\alpha 7$ KO FVB mice incubated with α -bgtx-affinity beads or control beads. For α -bgtx interactome investigations, wild-type C57Bl/6 α -

bgtx-affnity enrichments were compared to C57Bl/6 extracts incubated with control beads. Protein bound to α -bgtx-affnity beads was sequentially eluted with 2 M NaCl sodium chloride and 1 M carbachol, reduced, alkylated, and digested with trypsin in-solution. The resulting peptides were analyzed with an Orbitrap Fusion mass spectrometer, and spectra were identified using the Mascot algorithm. Data were analyzed further using ProteoIQ.

Figure 2.

α -bgtx-affinity immobilization conditions. (A) α -Bgtx-sensitive proteins were isolated from samples using wild-type mice and α -bgtx-conjugated affinity beads (i.e., α -bgtx beads). (B) Nonspecific interactions with α -bgtx beads were identified using α -bgtx binding enrichment in samples prepared from α 7 KO mice. (C) Sepharose without conjugated α -bgtx (i.e., “control beads”) were used to control for nonspecific interactions to Sepharose. (D) Sepharose without conjugated α -bgtx (i.e., “control beads”) were used to control for nonspecific interactions to Sepharose in α 7 KO mice samples.

Figure 3. Specific ^{125}I - α -bgtx binding to solubilized protein isolated from C57Bl/6 and FVB solubilized murine brain tissue. Binding of 5 nM ^{125}I - α -bgtx to protein immobilized on α -bgtx-affinity beads (4 mg α -bgtx per 1 g Sepharose) incubated with male C57Bl/6 (A) and FVB (B) solubilized murine whole brain membrane fractions. Nonspecific binding was determined by the addition of 1 μM unlabeled α -bgtx to preparations prior to the addition of ^{125}I - α -bgtx. Appreciable ^{125}I - α -bgtx binding was observed in both C57Bl/6 and FVB strains (5.4 ± 0.5 and 6.4 ± 1 fmol ^{125}I - α -bgtx per mg solubilized protein respectively). No appreciable binding was detected in either strain using control beads (A,B) or $\alpha 7$ KO FVB mice using α -bgtx-affinity beads (B). Three mice were used per condition, and extracts from each mouse were measured in duplicate. Significance between α -bgtx affinity pulldowns and

either control bead or α -bgtx pulldowns from $\alpha 7$ KO was determined using a Student's t-test. “*” denotes $p < 0.05$.

Figure 4.

Summary of identified interactomes. Three interactomes were identified and categorized as (A) $\alpha 7$ -nAChR, (B) non- $\alpha 7$ -nAChR, α -bgtx, or (C) α -bgtx interactomes. High-salt wash-eluted and carbachol-eluted fractions were investigated in (A) and (B). Only carbachol-eluted proteins were investigated in (C). The high-salt washes were investigated to identify interacting proteins eluted before the addition of carbachol. An $\alpha 7$ -nAChR subunit peptide was identified in the carbachol elutions of the $\alpha 7$ -nAChR as well as in the α -bgtx interactomes (denoted by the green arrows). Peptides corresponding to $\alpha 7$ -nAChR subunit were not identified in the high-salt wash fraction of the $\alpha 7$ -nAChR interactome, nor in either of the non- $\alpha 7$ -nAChR interactomes (red arrows). The total number of proteins identified using the defined inclusion criteria is listed on the right.

Figure 5.

Cellular compartments enriched in the $\alpha 7$ -nAChR interactome data identified using STRING. Proteins are identified by their gene name. GO Term identification numbers, false discovery rates, and individual matched protein names are included in Supplemental Tables S-2. Only matched cellular compartment ontologies <5% FDR are shown. Six ontologies described further in the text are highlighted in orange: mitochondrion, plasma membrane, neuron projection, cytoplasmic vesicle membrane, Golgi-associated vesicle, and endosome.

Figure 6. Molecular functions enriched in the $\alpha 7$ -nAChR interactome data identified using STRING. Proteins are identified by their gene name. GO term identification numbers, false discovery rates, and individual matched protein names are included in Supplemental Tables S-4. Only matched molecular function ontologies <5% FDR are shown. Two ontologies, tau (τ)-protein kinase activity and carbohydrate derivative binding, are highlighted in orange and described further in the text.

denoting cellular component include: mitochondrion (light green), plasma membrane (yellow), neuron projection (teal), cytoplasmic vesicle membrane (gold), endosome (purple), and cytoskeleton (blue).

Figure 8.

Comparison of the carbachol eluted proteins from the three identified interactomes. The number of α -bgtx interacting proteins identified in the α 7-nAChR interactome or the non- α 7-nAChR, α -bgtx interactome. No proteins were identified in both the α 7-nAChR and non- α 7-nAChR, α -bgtx interactomes.

Table 1.**Identification of $\alpha 7$ -nAChR and GABA_AR Subunits in Carbachol-Eluted Fractions^a**

	receptor subunit	accession number	experimental	control	total peptides	data sets (of 5)	probability score (%)
A	$\alpha 7$ neuronal acetylcholine receptor	P49582	FVB WT	$\alpha 7$ KO	1	3	100
B	$\alpha 7$ neuronal acetylcholine receptor	P49582	C57Bl/6 WT	control beads	1	2	100
C	$\beta 3$ γ -aminobutyric acid receptor	P63080	C57Bl/6 WT	control beads	3	3	100
D	$\beta 1$ γ -aminobutyric acid receptor	P50571	FVB $\alpha 7$ KO	control beads	2	3	100

^a Both $\alpha 7$ -nAChR-specific and α -bgtx-specific controls were investigated for all known α -bgtx binding proteins. (A) The $\alpha 7$ -nAChR subunit was identified comparing FVB wild-type and $\alpha 7$ KO brain tissue. (B, C) Both the $\alpha 7$ -nAChR subunit and a GABA_AR subunit were found in C57Bl/6 wild-type using control beads, i.e., beads lacking conjugated α -bgtx. (D) Only a GABA_AR subunit was found using control beads in $\alpha 7$ KO brain tissue. Probability scores were measured using the ProteinProphet algorithm integrated into ProteoIQ.

Table 2.

KEGG Pathway Analysis of the Identified $\alpha 7$ -nAChR Interactome^a

protein name (gene name, accession number)	unique peptides	seq cov. (%)	ion score	prob. Score (%)	KEGG pathway(s)
5-aminoimidazole-4-carboxamide ribonucleotide formyltransferase/IMP cyclohydrolase (Atic, Q9CWX9) ♦	2	6	68	96	mmu00230: purine metabolism, mmu00670: one-carbon pool by folate, mmu01100: metabolic pathways, mmu01130: biosynthesis of antibiotics
acetyl-Coenzyme A acetyltransferase 2 (Acat2, Q8CAY6) ♦	2	9	80	100	mmu00071: fatty acid degradation, mmu00072: synthesis and degradation of ketone bodies, mmu00280: valine, leucine and isoleucine degradation, mmu00310: lysine degradation, mmu00380: tryptophan metabolism, mmu00620: pyruvate metabolism, mmu00630: glyoxylate and dicarboxylate metabolism, mmu00640: propanoate metabolism, mmu00650: butanoate metabolism, mmu00900: terpenoid backbone biosynthesis, mmu01100: metabolic pathways, mmu01130: biosynthesis of antibiotics, mmu01200: carbon metabolism, mmu01212: fatty acid metabolism
acylglycerol kinase (Agl, Q9ESW4) ♦	2	9	89	100	mmu00561: glycerolipid metabolism, mmu01100: metabolic pathways
acylphosphatase 1, erythrocyte (common) type (Acyp1, P56376) ♦	1	14	69	100	mmu00620: pyruvate metabolism
adaptor-related protein complex 3, mu 1 subunit (Ap3m1, Q9JRC8)	2	8	99	99	mmu04142: lysosome
adenylate cyclase activating polypeptide 1 receptor 1 (Adeyap1r1, Q6NXJ9)	2	3	120	100	mmu04024: cAMP signaling pathway, mmu04080: neuroactive ligand-receptor interaction, mmu04713: circadian entrainment, mmu04911: insulin secretion, mmu04924: renin secretion
Araf proto-oncogene, serine/threonine kinase (Araf, P04627)	2	3	95	98	mmu04012: ErbB signaling pathway, mmu04068: FoxO signaling pathway, mmu04270: vascular smooth muscle contraction, mmu04650: natural killer cell mediated cytotoxicity, mmu04720: long-term potentiation, mmu04726: serotonergic synapse, mmu04730: long-term depression, mmu04810: regulation of actin cytoskeleton, mmu04910: insulin signaling pathway, mmu04914: progesterone-mediated oocyte maturation, mmu05034: alcoholism, mmu05160: hepatitis C, mmu05200: pathways in cancer, mmu05205: proteoglycans in cancer, mmu05210: colorectal cancer, mmu05211: renal cell carcinoma, mmu05212: pancreatic cancer, mmu05213: endometrial cancer, mmu05214: glioma, mmu05215: prostate cancer, mmu05218: melanoma, mmu05219: bladder cancer, mmu05220: chronic myeloid leukemia, mmu05221: acute myeloid leukemia, mmu05223: non-small cell lung cancer
asparagine synthetase (Asns, Q61024) ♦	2	4	89	100	mmu00250: alanine, aspartate and glutamate metabolism, mmu01100: metabolic pathways
ATP synthase, H ⁺ transporting, mitochondrial F0 complex, subunit F (Atp5j, P97450)	2	27	102	100	mmu00190: oxidative phosphorylation, mmu01100: metabolic pathways, mmu05010: Alzheimer's disease, mmu05012: Parkinson's disease, mmu05016: huntington's disease
CD81 antigen (Cd81, P35762) ♦	1	8	85	100	mmu04662: B cell receptor signaling pathway, mmu05144: malaria, mmu05160: hepatitis C
cholinergic receptor, nicotinic, alpha polypeptide 7 (Chma7, P49582)	1	4	67	100	mmu04020: calcium signaling pathway, mmu04080: neuroactive ligand-receptor interaction, mmu04725: cholinergic synapse, mmu05033: nicotine addiction, mmu05204: chemical carcinogenesis

protein name (gene name, accession number)	unique peptides	seq cov. (%)	ion score	prob. score (%)	KEGG pathway(s)
cleavage and polyadenylation specificity factor 3 (Cpsf3, Q9QXK7)	3	6	81	100	mmu03015: mRNA surveillance pathway
exocyst complex component 2 (Exoc2, Q9D4H1)	2	2	101	98	mmu04014: Ras signaling pathway
G1 to S phase transition 2 (Gsp12, Q149F3) ♦	2	6	53	100	mmu03015: mRNA surveillance pathway
gelsolin (Gsn, P13020) ♦	4	11	97	100	mmu04666: Fc gamma R-mediated phagocytosis, mmu04810: regulation of actin cytoskeleton, mmu05203: viral carcinogenesis
golgi apparatus protein 1 (Glg1, Q61543) ♦	2	2	111	100	mmu04514: cell adhesion molecules (CAMs)
HECT and RLD domain containing E3 ubiquitin protein ligase family member 1 (Herc1, E9PZP8)	2	0	80	98	mmu04120: ubiquitin-mediated proteolysis
heme oxygenase 2 (Hmox2, O70252) ♦	4	19	150	100	mmu00860: porphyrin and chlorophyll metabolism, mmu04978: mineral absorption
insulin-degrading enzyme (Ide, Q9JHR7)	3	3	110	98	mmu05010: Alzheimer's disease
kinesin family member 5A (Kif5a, P33175)	8	8	445	95	mmu04144: endocytosis, mmu04728: dopaminergic synapse
lamin A (Lmna, P48678) ♦	3	6	157	100	mmu05410: hypertrophic cardiomyopathy (HCM), mmu05412: arrhythmogenic right ventricular cardiomyopathy (ARVC), mmu05414: dilated cardiomyopathy
neurexin III (Nrxn3, Q6P9K9)	2	2	88	98	mmu04514: cell adhesion molecules (CAMs)
neuropilin 1 (Nrp1, P97333) ♦	1	2	67	100	mmu04360: axon guidance, mmu05166: HTLV-I infection
neurotrophic tyrosine kinase, receptor, type 2 (Ntrk2, P15209) ♦	5	10	225	100	mmu04010: MAPK signaling pathway, mmu04722: neurotrophin signaling pathway, mmu05034: alcoholism
nucleoporin 210 (Nup210, Q9QY81)	1	1	53	96	mmu03013: RNA transport
nucleoporin 62 (Nup62, Q63850) ♦	2	5	61	93	mmu03013: RNA transport
prolactin regulatory element binding (Preb, Q9WUQ2)	4	11	180	100	mmu04141: protein processing in endoplasmic reticulum
proteasome (prosome, macropain) sub-unit, alpha type 7 (Psm7, Q9Z2U0)	4	15	147	100	mmu03050: proteasome
protein kinase C, delta (Prkcd, P28867) ♦	1	2	52	99	mmu04062: chemokine signaling pathway, mmu04270: vascular smooth muscle contraction, mmu04530: tight junction, mmu04666: Fc gamma R-mediated phagocytosis, mmu04722: neurotrophin signaling pathway, mmu04750: inflammatory mediator regulation of TRP channels, mmu04912: GnRH signaling pathway, mmu04915: estrogen signaling pathway, mmu04930: type II diabetes mellitus, mmu04931: insulin resistance
protein kinase, AMP-activated, alpha 1 catalytic subunit (Prkaa1, Q5EG47)	2	6	68	96	mmu04068: FoxO signaling pathway, mmu04140: regulation of autophagy, mmu04150: mTOR signaling pathway, mmu04151: PI3K-Akt signaling pathway, mmu04152: AMPK signaling pathway, mmu04710: circadian rhythm, mmu04910: insulin signaling pathway, mmu04920: adipocytokine signaling pathway, mmu04921: oxytocin signaling pathway, mmu04922: glucagon signaling pathway, mmu04931: insulin resistance, mmu04932: nonalcoholic fatty liver disease (NAFLD), mmu05410: hypertrophic cardiomyopathy (HCM)

protein name (gene name, accession number)	unique peptides	seq cov. (%)	ion score	prob. Score (%)	KEGG pathway(s)
protein phosphatase 1, regulatory (inhibitor) subunit 3F (Ppp1r3f, Q9JIG4)	2	5	77	99	mmu04910: insulin signaling pathway
ribosomal protein S17 (Rps17, P63276)	3	40	84	94	mmu03010: ribosome
Sec24 related gene family, member D (S. cerevisiae) (Sec24d, Q6NXL1)	2	3	98	100	mmu04141: protein processing in endoplasmic reticulum
solute carrier family 32 (GABA vesicular transporter), member 1 (Slc32a1, O35633) ♦	1	2	71	100	mmu04721: synaptic vesicle cycle, mmu04723: retrograde endocannabinoid signaling, mmu04727: GABAergic synapse, mmu05032: morphine addiction, mmu05033: nicotine addiction
squamous cell carcinoma antigen recognized by T cells 1 (Sart1, Q9Z315) ♦	1	2	72	100	mmu03040: spliceosome
synaptic Ras GTPase activating protein 1 homologue (rat) (Syngap1, F6SEU4)	2	3	76	97	mmu04014: Ras signaling pathway
talin 1 (Tln1, P26039)	7	3	299	92	mmu04015: Rap1 signaling pathway, mmu04510: focal adhesion, mmu04611: platelet activation, mmu05166: HTLV-I infection
ubiquitination factor E4A (Ube4a, E9Q735) ♦	2	3	95	100	mmu04120: ubiquitin-mediated proteolysis
ubiquitination factor E4B (Ube4b, Q9ES00) ♦	1	2	52	98	mmu04120: ubiquitin-mediated proteolysis, mmu04141: protein processing in endoplasmic reticulum
voltage-dependent anion channel 2 (Vdac2, Q60930)	2	8	107	100	mmu04020: calcium signaling pathway, mmu04022: cGMP-PKG signaling pathway, mmu05012: Parkinson's disease, mmu05016: Huntington's disease, mmu05166: HTLV-I infection
WAS protein family, member 3 (Wasf3, Q8VHI6)	1	4	95	100	mmu04520: adherens junction, mmu04666: Ec gamma R-mediated phagocytosis, mmu05231: choline metabolism in cancer
zyxin (Zyx, Q62523) ♦	1	3	66	100	mmu04510: focal adhesion

^a 42 of the 121 total interacting proteins were characterized with KEGG pathway terms using DAVID. Proteins are identified by protein name, and gene name, accession numbers. The number of unique peptides, sequence coverage (seq. cov. %), ion scores, and probability (prob. score %) for each protein is provided. High-salt wash-eluted proteins are identified with "♦".

^aProteins associated with Alzheimer's disease (AD), insulin resistance (IR), and/or Parkinson's disease (PD). These interactions are related to these pathologies either directly by the protein or through genetic association. Proteins are identified by protein name, gene name, and accession numbers. The number of unique peptides, sequence coverage (seq. cov. %), ion scores, probability (prob. score %), and the associated disease are all indicated. High-salt-wash-eluted proteins are identified with "♦". AD, IR, and PD columns provide references for examples of associations of each protein with the specified disease state.
